Abstract

The Arctic Ocean contains only a 1% of the world's ocean water, but the rivers that flow out into it account for the 10% of the volume world's rivers freshwater. The upper layer of fresher water facilitates the creation of sea ice and plays an important role in the position of the jet stream and storms over the northern hemisphere [ISBN, 978-82-7971-097-4]. Remote sensing measurements are of special importance in the Arctic since in situ data is very scarce there. SMOS and SMAP are currently providing sea surface salinity (SSS) measures, but only the product provided by Barcelona Expert Center (BEC) is a dedicated product for the Arctic region. The product that we present in this work is an improvement of the BEC Arctic v2.0. The new version 3.0 has as the primary objective the describing better the river discharges. The spatial grid used is WGS84/NSIDC EASE-Grid 2.0 North for the all stages of the processing chain. This procedure avoids spatial interpolation, favoring the definition of river mouths. The salinity retrieval is based on the Debiased non-bayesian method [doi:10.1016/j.rse.2017.02.023] and similarly to what is done in the processing of altimetric data, SMOS salinity is corrected using a reference calculated from the own SMOS data for each latitude, longitude, pass orientation and antenna measuring position. Arctic v3.0 differs from current method [doi:10.3390/rs10111772] in two important points: the reference is computed for brightness temperature instead of SSS and the antenna has been divided in a more homogeneous grid. Other improvements concern to data filtering and propagation of the radiometric errors to SSS. All these improvements provide level 3 maps less noisy, increasing the effective resolution of salinity gradients. Freshwater gradients are much better resolved than in previous version (Fig. 1). Comparison with JPL SMAP product is also planned as a first step to generate a combined product. This work is funded by ESA Arctic + project and also includes the assimilation of the resulting SSS product in the ocean-sea ice data assimilation system TOPAZ as the next version TOPAZ5. A preliminary study [doi:10.5194/os-2018-163] has been performed concluding that BEC product could be a good candidate to be assimilated by TOPAZ. Moreover, some preliminary tests with a pre-release v3.0 version will start shortly.

Arctic+ salinity is an ESA's Invitation To Tender devoted to provide a better description of salinity gradients, freshwater fluxes and currents than the obtained until now from SMOS derived products. The result is a product capable of characterize the Arctic salinity and monitor some aspects of the climate change.

Arctic+ salinity ITT started in December 2018 and it will finish in June 2020. Now we are presenting the resulting salinity product that will be freely distributed in January. The next step is to provide specific studies about the Arctic.

Stay tuned to our oral contribution in Ocean Sciences Meeting 2020!

Data distribution

Barcelona Expert Center

Arctic+ salinity product will be publicly available in January. Our distribution list is open to inform about news concerning this and other products.

Our products are distributed by ftp. You can freely register to this service.

Arctic+ salinity daily 9-day maps will be distributed in WGS 84 / NSIDC EASE-Grid 2.0 North EPSG:6931 (25 km) for years 2011-2019.

2015 Ob' run off

Extreme 2015 run off of Ob river seems to be originated by continental melting. Probably linked to abnormally high temperatures in summer.

AGU100 ADVANCING EARTH AND SPACE SCIENCE

AGU FALL MEETING — Thursday, 12 December 2019

SMOS MISSION providing L-band data since 2010

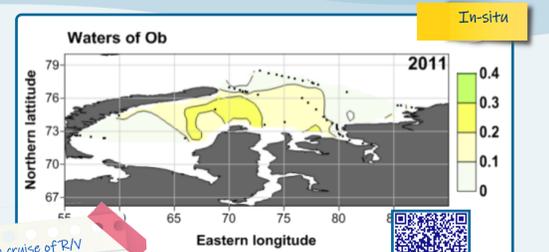

Soil Moisture and Ocean Salinity (SMOS) mission is measuring those variables from space since 2010.

SMOS, launched on 2 November 2009, is one of the ESA's Earth Explorer missions. Its single payload, the Microwave Imaging Radiometer by Aperture Synthesis radiometer (MIRAS), is the first 2D synthetic aperture interferometric radiometer in space. It operates in L-band at 1.413 GHz.

SMOS provides brightness temperature 2D images about 1400 km wide every 1.2 seconds.
