## Abstract

GOSAT and GOSAT-2 have simultaneously observed both reflected SWIR solar light and TIR emissions with a single FTS mechanism with the Thermal And Near-infrared Sensor for carbon Observation Fourier-Transform Spectrometer (TANSO-FTS) and TANSO-FTS-2 since 2009 and 2018, respectively. Their linear polarization bands provide information on light-path modification and make accurate remote sensing possible, even under aerosol and thin-cloud contaminated conditions. We can retrieve the difference between the partial column-averaged dry-air mole fractions of the two individual layers of lower and upper troposphere (LT and UT) by combining TIR and SWIR spectra data simultaneously, thereby constraining the accurate total column density of XCO<sub>2</sub> and XCH<sub>4</sub>. TANSO-FTS has a two-axis agile pointing system, which allows cross-track and along-track motions. It was originally designed for grid scan observations and viewing onboard calibration sources. After the pointing mechanism was switched from primary to secondary on 26 January 2015, We decided to make more frequent target observations, by uploading AT and CT pointing angles and observation timing as commands from the ground every day. About 1000 locations are allocated to target observations such as calibration and validation site, megacities, or large emission sources. We define vertical layers of LT and UT not by temperature, but by the retrieved P<sub>surf</sub> from individual O<sub>2</sub> A band data. The pressure-height ranges of the LT and UT were taken as 0.6–1 P<sub>surf</sub> and 0.2–0.6 P<sub>surf</sub>, respectively. As the LT includes the entire boundary layer, analysis using XCO<sub>2</sub> (LT) and XCH<sub>4</sub> (LT) can double the signal of local emissions and remove the effects of CO<sub>2</sub> and CH<sub>4</sub> variability in the UT, which typically extends over a much wider area. We have targeted intense measurements over mega cities since 2016. We assume the average density of the upper troposphere is a background. We define XCO<sub>2</sub> anomalies XCO<sub>2</sub>(LT)-XCO<sub>2</sub>(UT average), which show enhancement caused by local anthropogenic emissions. In 2020, we detected lower anomalies than previous years over mega cities such as Tokyo, Beijing, and New York.

# ENHANCEMENT OF LOWER TROPOSPHERE DENSITY OVER ANTHROPOGENIC EMISSION SOURCES

## (1) Intense Measuremnt over Mega Citeis

Average monthly abundances of CO<sub>2</sub> in the lower troposphere for the past 4 years (upper) and 2020 (lower) from GOSAT of greater Tokyo and Beijing.

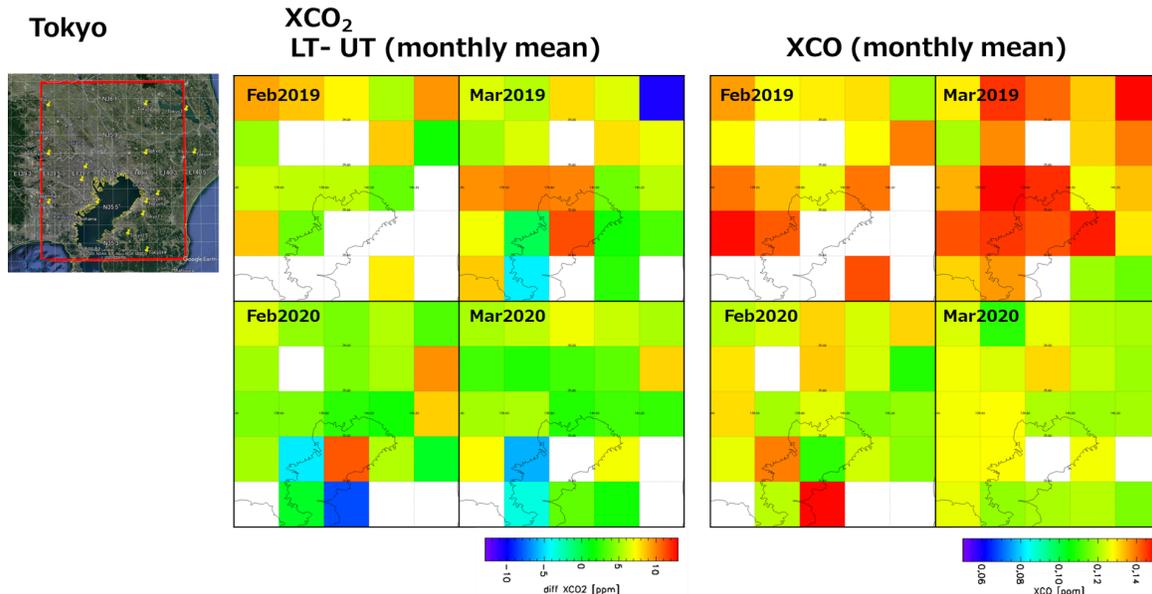

CO<sub>2</sub> has accumulated in the atmosphere since the Industrial Revolution. We assume the average density of the upper troposphere is a background.

XCO<sub>2</sub> anomaly: XCO<sub>2</sub>(LT)-XCO<sub>2</sub>(UT<sub>average</sub>), Partial column of lower troposphere (0-4 km)– Monthly-Area averaged upper troposphere (4-12 km)

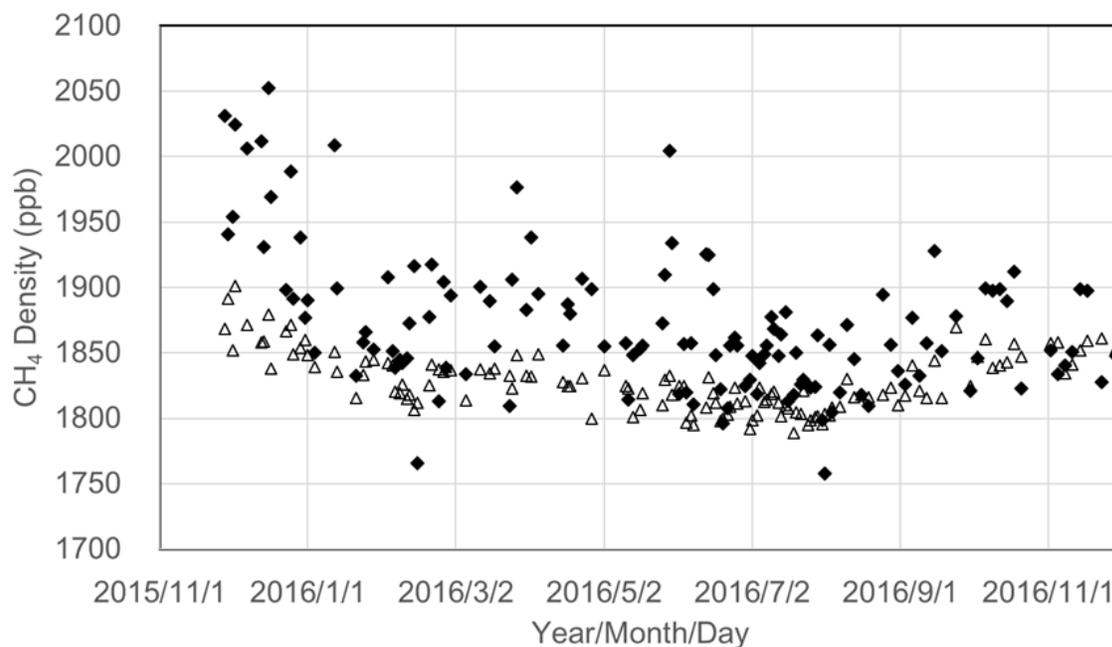

## (2) More intense sampling by GOSAT-2

With wider pointing range, GOSAT-2 can provide more intense data over megacities. It also provide CO in addition to CO<sub>2</sub>

(3) XCH<sub>4</sub>(LT) and XCH<sub>4</sub>(UT) at Aliso Canyon CA

CH<sub>4</sub> total partial column-averaged dry-air mole fractions (XCH<sub>4</sub>) (triangles) and the lower troposphere (XCH<sub>4</sub> (LT)) (diamonds) at Aliso Canyon.

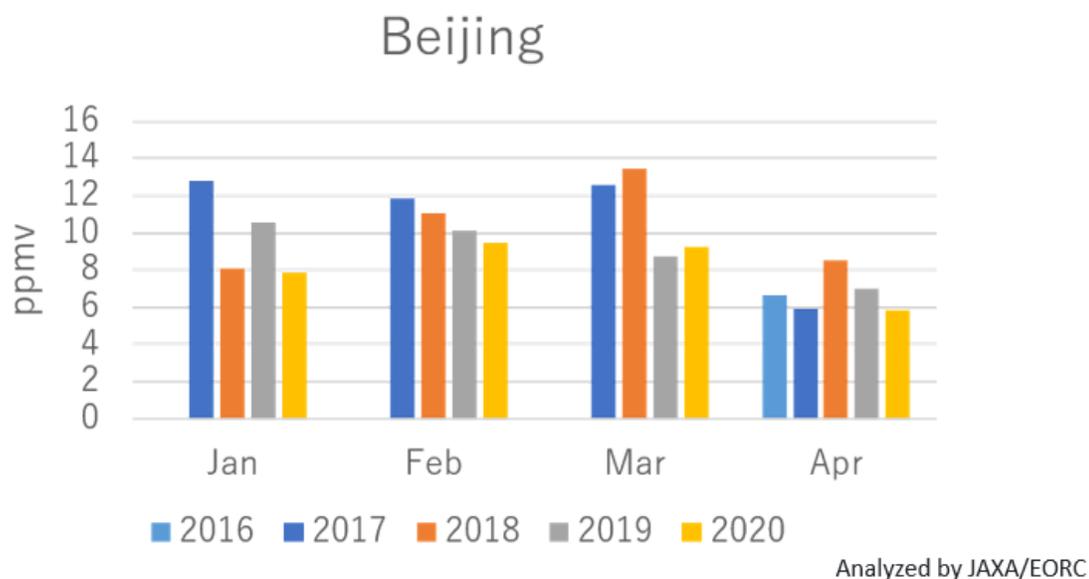

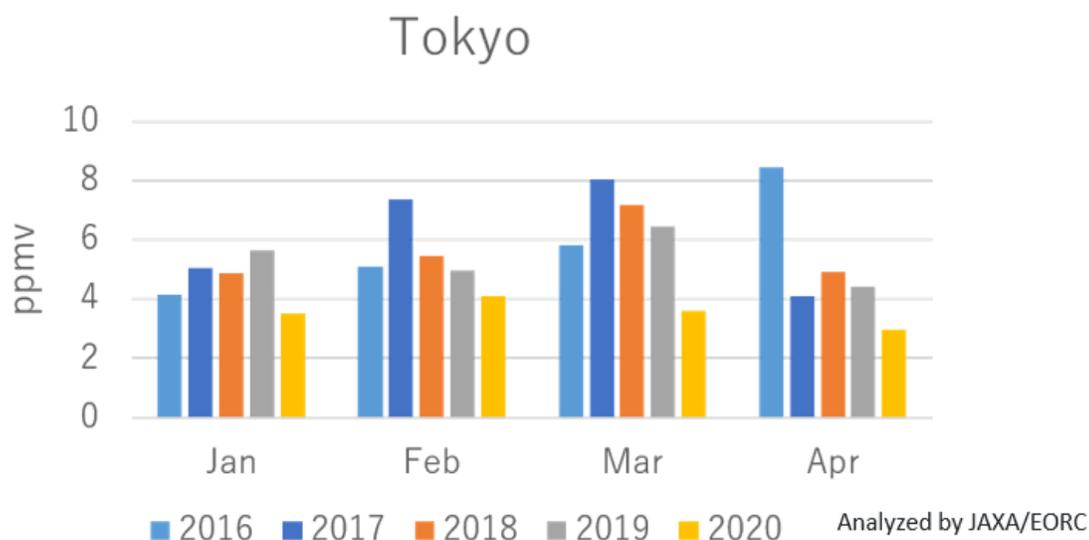

(Kuze et al., 2020, Remote Sensing)

# APPLICATIONS TOWARD GLOBAL STOCK TAKE: MONITORING COVID-19 AND CH4 LEAK EVENT

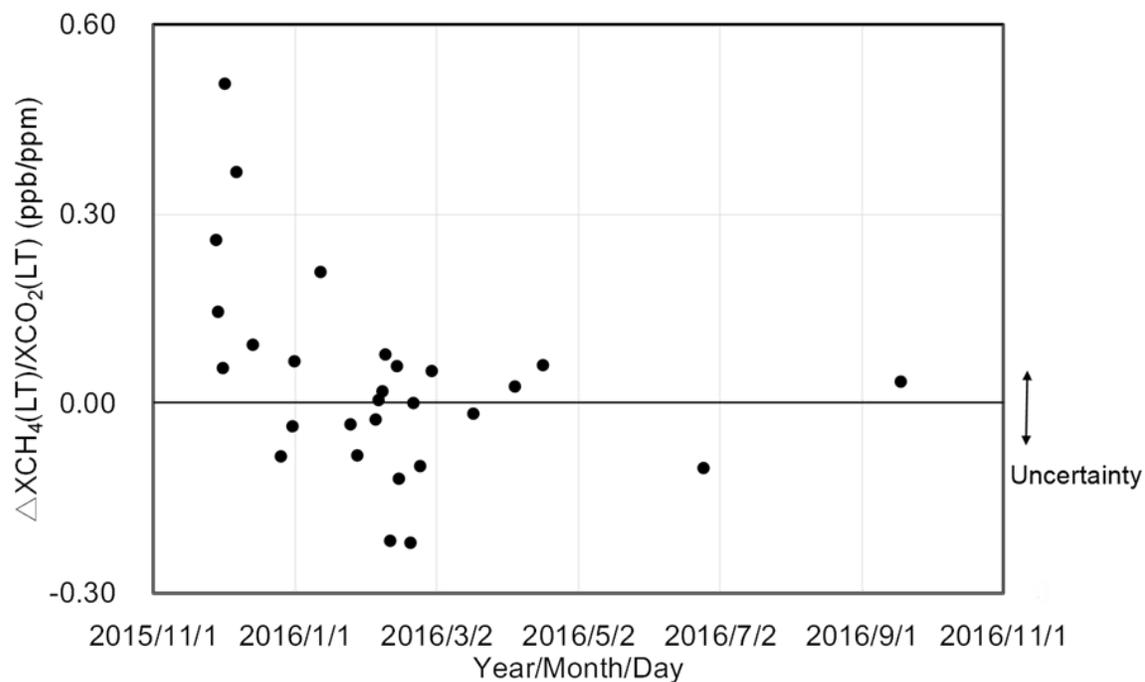

<Before and After COVID19>

The difference in CO<sub>2</sub> density in the upper and lower troposphere is smaller in 2020 compared to 2016-2019 in Tokyo and Beijing.

<Monitoring Natural Gas CH<sub>4</sub> leak Monitoring>

XCH<sub>4</sub> (LT) enhancements in Aliso Canyon with time normalized with XCO<sub>2</sub> (LT) between the blowout and leak control. Data with wind direction of East–South–Northwest at the leak point were filtered out.

(Kuze et al., 2020, Remote Sensing)

<Next: Contribution to Paris Agreement>

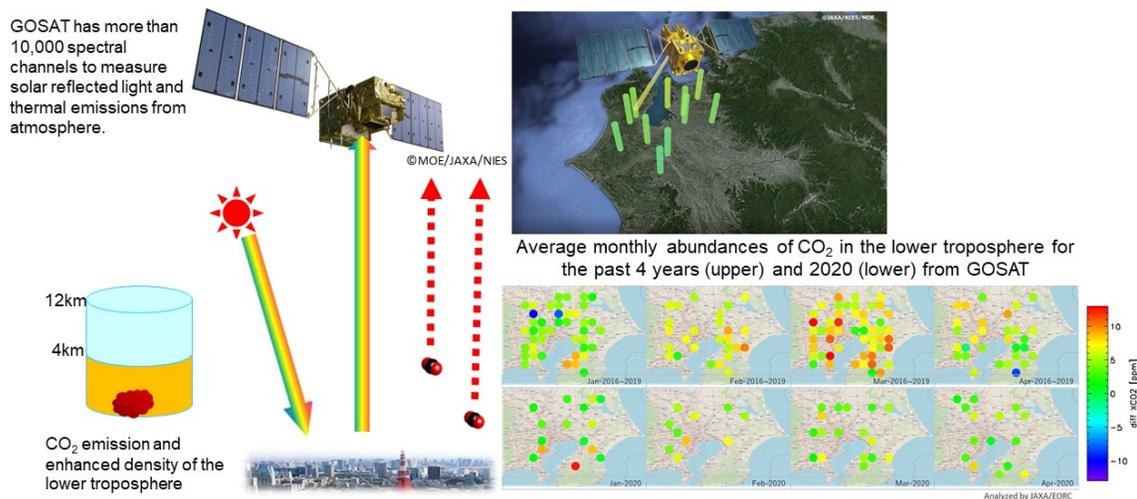

- Consider whether temporary reductions in CO2 emissions due to COVID-19 restrictions have impacts on lowering the global carbon footprint.
- Continue and extend target observations to more than 50 cities.
- Estimate GHG emissions from individual source sectors such as power plant, transport, industries.
- Contribute to the Global Stocktake of the Paris Agreement.

## AUTHOR INFORMATION

Kuze has been involved in the Greenhouse gases Observing Satellite (GOSAT) project for 18 years for developing on-board instruments, calibrations and operation, Level 0-1 processing of GOSAT data and the GOSAT Level 1 products. Now he is the GOSA-2 project manager. He is also involved in the feasibility study on an air-borne compact imaging spectrometer with angstrom spectral resolution for greenhouse gases, air quality and chlorophyll fluorescence measurements. When he was at Smithsonian astrophysical observatory, he was involved in cloud detection of GOME and SCIAMACHY.

# ABSTRACT
