Abstract

Background The WHO recommends testing any suspected person with Severe Acute Respiratory Syndrome CoronaVirus-2 (SARS-CoV-2), in order to limit the spread of the epidemic. In Italy, some Regions opted for extensive testing, whereas others limited tests to selected subjects. To assess the influence of different strategies, we examined the incidence of death and severe cases in Italy. **Methods** Data on new cases of SARS-CoV-2, number of tests, deaths, and admissions to Intensive Care Units (ICU) were retrieved in each Italian Region, from February 24th to March 18th, 2020. As an index of different screening strategies, the number of tests/positive test results (T/P) ratio as of March 7th, 2020, was considered. The cumulative number of deaths and of new severe cases, between March 23th and 25th was recorded. The association of those two outcomes with the number of T/P ratio was assessed using linear regression models. **Results** In the interval between March 23th-25th, recorded deaths (*million inhabitants) were 14(3-54), whereas severe cases were 31(10-112). Both the number of deaths and that of severe cases showed a significant correlation (R^2 .38 and .37, with $p < .01$) with the T/P ratio. Deaths and severe cases were associated with higher mean personal income and lower density of General Practitioners (GPs). The association of T/P with severe cases and deaths retained statistical significance after adjusting for mean personal income (R^2 .20 and .21, respectively; both $p = .04$) and GPs density (R^2 .22 and .21, respectively; both $p = .03$). **Conclusions** A more aggressive screening strategy for SARS-Cov-2, was associated with lower rates of death and severe disease in Regions of Italy.

Introduction

The World Health Organization recommends to test any suspected person with Severe Acute Respiratory Syndrome CoronaVirus-2 (SARS-CoV-2)¹, in order to isolate positive individuals, limiting the spread of the epidemic. On the other hand, extensive isolation of oligosymptomatic infected people and of their close contacts, including many healthcare professionals, could reduce the efficiency of healthcare systems in responding to the epidemic. These different viewpoints are currently debated in Italy, where the healthcare system has a Regional organization; different Regions have adopted opposite strategies in this respect. Some Regions (e.g., Veneto) opted for extensive testing, thus organizing laboratory facilities, whereas others (e.g., Lombardia, Emilia-Romagna, and Piemonte) limited diagnostic tests to selected subjects. Conversely, social distancing and isolation measures (including lockdown) were decided at a National level. To assess the potential influence of different testing strategies, we examined the incidence of death and severe cases in 19 regions of Italy.

Methods

We retrieved daily data on new cases of SARS-CoV-2 (i.e., individuals with positive test results), number of tests (reverse transcription polymerase chain reaction; RT-PCR) performed, deaths, and admissions to Intensive Care Units (ICU) in each Region, from February 24th to March 18th, 2020, obtained from the

Health Ministry website². Demographic, socioeconomic and healthcare organization data were retrieved from the National Institute of Statistics (ISTAT)³.

As an index of different screening strategies, the number of tests/positive test results (T/P) ratio as of March 7th, 2020, was considered. The subsequent evolution of the epidemic was assessed through the cumulative number of deaths and of new severe cases, between March 23th and 25th, inclusive; the latter were defined as a composite of death and admission to ICU. This work is based on publicly available data, needing no ethical approval.

The association of those two outcomes with the number of T/P ratio at March 7th was assessed using a linear regression model. For each confounder significantly associated with outcomes, multivariate linear regression models were applied to assess the independent contribution of T/P, assuming two-sided $p < .05$ as significant. Analyses were performed on SPSS (SPSS-Inc., Chicago, IL, USA) 25.0.

Results

The median number of tests per million inhabitants performed as of March 7th in different Regions (with interquartile range) was 240 (105-474), ranging from 58 to 2941. The median prevalence of known SARS-CoV-2 infection was 27 (7-64) cases per million, ranging from 2 to 273. The number of tests and that of individuals with positive test results showed a significant correlation ($r=0.61$, $p=0.006$). The T/P ratio was 11.2 (5.0-19.8), with a range of 3.6-28.2. In the interval between March 23th and 25th, recorded deaths per million inhabitants were 14(3-54), with a range of 2-119, whereas severe cases (ICU+death) were 31(10-112), ranging from 4 to 271. Both the number of deaths and that of severe cases on March 23th-25th showed a significant correlation (R^2 .38 and .37, with $p=.004$ and .006, respectively) with the T/P ratio up to March 7th (Figure 1). With the exclusion of apparent outlier Lombardia, R^2 for the correlation of deaths and severe cases were .36 ($p=.009$) and .34 ($p=.01$), respectively.

Deaths and severe cases were associated with higher mean personal income and lower density of General Practitioners (GPs); deaths were also associated with higher population density (Table 1). The association of T/P with severe cases and deaths retained statistical significance after adjusting for mean personal income (R^2 .20 and .21, respectively; both $p=.04$) and GPs density (R^2 .22 and .21, respectively; both $p=.03$).

Discussion

A higher number of tests/positive test results ratio, reflecting a more aggressive screening strategy for SARS-Cov-2, was associated with lower rates of death and severe disease in Regions of Italy. Although the association was maintained after adjusting for some confounders, the possibility of other unaccounted confounders cannot be excluded. Moreover, results are specific for the time range considered. Despite these limitations, this association should be considered by policy-makers in other Countries faced by the threat of the epidemic.
