1 **Abstract**

2 Healthy pregnancy is accompanied by various immunological and metabolic adaptations.
3 Maternal obesity has been implicated in adverse pregnancy outcomes such as miscarriage,
4 preeclampsia, and gestational diabetes mellitus (GDM), while posing a risk to the neonate.
5 There is a lack of knowledge surrounding obesity and the maternal immune system. The
6 objective of this study was to consider if immunological changes in pregnancy are sabotaged
7 by maternal obesity.

8 Peripheral blood was collected from fasted GDM-negative pregnant women at 26-28 weeks
9 of gestation. Analysis was done using immunoassay, flow cytometry, bioenergetics analysis
10 and cell culture.

11 The plasma profile was significantly altered with increasing BMI, specifically leptin ($r=0.7635$),
12 MCP-1 ($r=0.3024$) and IL-6 ($r=0.4985$). Circulating leukocyte populations were also affected
13 with changes in the relative abundance of intermediate monocytes ($r=-0.2394$), CD4:CD8 T
14 cell ratios ($r=0.2789$), and NKT cells ($r=-0.2842$). Monocytes analysed in more detail revealed
15 elevated CCR2 expression and decreased mitochondrial content. However, LPS-stimulated
16 cytokine production and bioenergetic profile of MNCs was not affected by maternal BMI. The
17 Th profile skews towards Th17 with increasing BMI; Th2 ($r=-0.3202$) and Th9 ($r=-0.3205$) cells
18 were diminished in maternal obesity, and CytoStimTM-stimulation exacerbates IL-6
19 ($r=0.4166$), IL-17A ($r=0.2753$), IL-17F ($r=0.2973$) and IL-22 ($r=0.2257$) production with BMI,
20 while decreasing IL-4 ($r=-0.2806$).

21 Maternal obesity during pregnancy creates an inflammatory microenvironment. Successful
22 pregnancy requires Th2-biased responses yet increasing maternal BMI favours a Th17
23 response that could be detrimental to pregnancy. Further research should investigate key
24 populations of cells identified here to further understand the immunological challenges that
25 beset pregnant women with obesity.

1 **Introduction**

2 Maternal obesity during pregnancy is associated with adverse pregnancy outcomes such as
3 miscarriage ¹, preeclampsia ² and gestational diabetes mellitus ³, and poses an increased risk
4 to the offspring of fetal mortality and childhood obesity as a result of macrosomia and
5 metabolic syndromes ⁴. With the prevalence of obesity in women of reproductive age recently
6 reported as between 20% and 28% in England ⁵, reflecting the increasing prevalence of
7 obesity worldwide, maternal obesity and the health consequences for mother and child are
8 an endemic problem. In the not pregnant general population, we have good mechanistic
9 insight into the links between excessive fat accumulation, systemic low-grade inflammation,
10 and obesity-associated health risks such as type 2 diabetes mellitus (T2DM), reproductive
11 dysfunction and cardiovascular disease ⁶⁻⁸. Elevated circulating inflammatory markers such as
12 IL-6, TNF and C-reactive protein (CRP) characterise the systemic inflammation that typically
13 occurs with increasing adiposity ⁹. The current COVID-19 pandemic highlights the detrimental
14 impact of obesity on inflammation, immune function, and risk from infectious disease with,
15 for example, obesity and high CRP levels an indicator for severity of COVID-19 symptoms ¹⁰.

16

17 How obesity in pregnancy might mechanistically underpin the well documented adverse
18 pregnancy and child health outcomes is relatively unknown. The effects of maternal obesity
19 on inflammation and immune function in the term placenta ¹¹ and first trimester uterus ¹²
20 have received some attention revealing impact on immune cell number and function that
21 could contribute to adverse pregnancy outcomes. This includes depleted decidual
22 macrophages ¹³ and increased numbers of placental macrophages in obesity ¹¹, although
23 there are some conflicting findings regarding the number of placental macrophages with
24 maternal obesity ¹⁴. Maternal obesity also diminishes the numbers of uterine resident NK cells

OBESITY AND THE MATERNAL IMMUNE SYSTEM

25 and alters their contribution to extracellular matrix remodelling and growth factor signalling
26 to compromise trophoblast survival and spiral artery remodelling¹². In contrast, the systemic
27 effects of obesity in pregnant women are largely unknown. Like the general population,
28 maternal IL-6, CRP and leptin levels are elevated in pregnant women with obesity compared
29 to their lean counterparts^{14, 15}. This suggests a common outcome of systemic inflammation
30 in pregnant and not pregnant adults with obesity. It also highlights that obesity-related
31 changes can occur over and above the systemic inflammatory alterations that are a normal
32 feature of pregnancy, including reduced pro-inflammatory cytokines (e.g. IL-6, CCL2, CXCL10,
33 IL-18, TNF) and increased immunomodulatory and anti-inflammatory mediators (e.g. soluble
34 TNF-receptor I, sTNF-RII, IL-1 Receptor Agonist (RA))¹⁶. Pregnancy per se is also associated
35 with cellular changes linked to inflammation and innate immune function such as increases
36 in peripheral blood neutrophils and monocytes for example¹⁷; maternal obesity exacerbates
37 the neutrophil count even further¹⁸. Functional effects have also been described and include
38 evidence of monocyte activation such as increased expression of CD14, CD64 and CD11b and
39 heightened production of oxygen free radicals¹⁹. In the general population, monocytes seem
40 particularly susceptible to the effects of obesity including increases in the non-classical subset
41 of monocytes²⁰, elevated expression of CCR2 by classical and intermediate monocytes and
42 higher expression of CX₃CR1 by all three subsets likely leading to increased intrinsic migratory
43 capacity in response to chemokines such as CX₃CL1 and CCL2 secreted by adipose tissue²¹.
44 Beyond reported increased production of LPS-stimulated IL-1 β and RANTES and ssRNA-
45 stimulated TNF and IL-10 in monocytes of the general population with obesity²¹ little is known
46 about the effects of maternal obesity on myeloid effectors of innate immunity and
47 inflammation. One recent study has shown that at term, monocytes of pregnant women with
48 obesity appear to be disrupted in their ability to adapt to pregnancy, perhaps explaining their

OBESITY AND THE MATERNAL IMMUNE SYSTEM

49 increased susceptibility to infections ²². With both atypical levels of circulating pro-
50 inflammatory cytokines such as IL-6 ²³ and exacerbated activation and maturation of
51 monocytes to the non-classical subset ²⁴ linked to preeclampsia for which obesity is a risk
52 factor ²⁵, there is real need to address this shortcoming.

53

54 Obesity in the general population is also recognised to negatively affect the function of
55 multiple lymphocyte populations. This ranges from suppression of T and natural killer (NK)
56 cell function – including reductions in cytotoxicity, IFN γ production and expression of perforin
57 and granzymes ²⁶ - and altered B cell activity that manifests as reduced class-switching and
58 immunoglobulin activity ²⁷. A reduced CD8+ T cell count in peripheral blood with obesity in
59 both the general population ²⁸ and pregnant women ²⁹ has been described and possibly links
60 to their accumulation in adipose tissue that, from mouse models, precedes that of
61 macrophages ²⁸. The cytokine producing capacity of T cells also changes with obesity in the
62 general population and obesity-associated inflammation is in part driven by a shift to Th1 and
63 Th17 which is thought to be mediated by leptin ³⁰. Th1 and Th17 cytokines such as TNF and
64 IFN γ are detrimental to pregnancy ³¹. Conversely, a Th2 and regulatory T cell (Treg) dominated
65 environment is considered essential to pregnancy success ³¹. Maladaptation of adaptive
66 immune processes could very much underpin obesity-associated adverse obstetric outcomes
67 with upregulation of Th1 described in GDM ³².

68

69 Here, we describe the changes in the immune environment of GDM-negative, pregnant
70 women of differing pre-pregnancy BMI at 28 weeks of gestation and reveal a phenotype of
71 systemic inflammation, monocyte activation and altered Th1/Th2/Th17 balance.

72

73 **Materials and Methods**

74 **Human peripheral blood mononuclear cells (PBMCs) isolation**

75 Human peripheral blood was collected from healthy, fasted pregnant women into one 9 ml
76 heparinised Vacuette™ and one 4 ml EDTA Vacuette™ (Greiner Bio-one, Frickenhausen,
77 Germany), and processed within 30 minutes of collection. Women were tested for gestational
78 diabetes mellitus (GDM) and all participants obtained a negative result from the oral glucose
79 tolerance test (OGTT). All samples were collected with informed written consent and ethical
80 approval obtained from a Health Research Authority Research Ethic Committee
81 (19/LO/0722). The demographics of the women whose samples were used are shown in table
82 1.

83

84 EDTA anti-coagulated blood was centrifuged at 1800 x *g* for 10 min at room temperature and
85 the plasma removed and stored at -80°C for cytokine and chemokine analysis.

86

87 The heparinised blood was first diluted 1 in 4 with PBS before layering onto 15 ml of
88 Lymphoprep™ (Stem Cell Technologies, UK) and centrifugation at 400 x *g* for 40 min at room
89 temperature. MNCs were extracted and washed with RPMI 1640 (Life Technologies, Paisley,
90 UK) twice by centrifugation at 515 x *g*. MNCs were used directly for flow cytometry or
91 stimulated with lipopolysaccharide (LPS; 10 ng/ml, Invitrogen) or CytoStim™ (Miltenyi Biotec,
92 UK) in RPMI 1640, 10% fetal bovine serum (FBS; Hyclone, Cytiva) and 2-mercaptoethanol at
93 37°C in 5% CO₂-in-air for 24 h; an unstimulated control was included. Cell free supernatants
94 were harvested and stored at -20°C for cytokine analysis.

95

96 **Bioenergetic analysis**

97 Bioenergetic analysis of MNCs was carried out using the Seahorse Extracellular Flux Analyser
98 XF^e96 (Agilent Technologies). MNCs (2.0×10^5 cells/well) in XF assay media minimal DMEM
99 (Agilent) supplemented with 5.5 mM glucose (Agilent), 1 mM pyruvate (Agilent) and 2 mM
100 glutamine (Sigma) were seeded onto a Cell-Tak (Corning) coated microplate³³. Parameters
101 for oxidative phosphorylation (OXPHOS) and glycolysis were measured simultaneously via
102 oxygen consumption rate (OCR; pmoles/min) and extracellular acidification rate (ECAR;
103 mpH/min) respectively with use of injections: oligomycin (1 μ M), FCCP (1 μ M), antimycin A
104 and rotenone (both 1 μ M) and monensin (20 μ M) (all from Sigma).

105

106 **Cytokine analysis**

107 *LEGENDplexTM*

108 Cytokine analysis was done via a multiplex approach using kits from BioLegend. The pre-
109 defined panels used were: 13-plex human Inflammation 1 panel (MNC cultures with LPS), 12-
110 plex human T-helper cytokine panel version (MNC cultures with CytoStimTM), and a 4-plex
111 human diabetes panel (plasma). These were performed according to the manufacturer's
112 instructions, with cultures containing LPS diluted 1:3, and the plasma and CytoStimTM run
113 neat.

114 *ELISA*

115 Plasma levels of IL-6, IL-8 TNF α and MCP-1 were measured using Human Quantikine[®] High
116 Sensitivity ELISA kits (Quantikine, Bio-Techne) according to the manufacturer's guidelines.

117

118 **Flow Cytometry**

119 Whole blood populations were first analysed using an 8-colour immunophenotyping kit,
120 human (Miltenyi Biotec, UK). This cocktail contains: anti-CD3 PE (IgG1, clone REA613), anti-

OBESITY AND THE MATERNAL IMMUNE SYSTEM

121 CD4 VioBright™ 667 (IgG1, clone REA623), anti-CD8 APC-Vio® 770 (IgG1, clone REA734), anti-
122 CD14 VioBlue® (IgG1, clone REA599), anti-CD16 VioBright 515 (IgG1, clone REA423), anti-
123 CD19 PE-Vio 770 (IgG1, clone REA675), anti-CD45 VioGreen™ (IgG1, clone REA747), anti-
124 CD56 VioBright 515 (IgG1, clone REA196).

125

126 Monocytes within MNC preparations were characterised using anti-CD14 Alexa Fluor® 647
127 (IgG1, clone 63D3, BioLegend) and anti-CD16 VioBlue® (IgMκ, clone VEP13, Miltenyi).
128 Mitochondrial content of monocytes was monitored using 2 nM MitoTracker Green (Life
129 Technologies). Expression of phenotypic markers were assessed using anti-CD11b PE (IgG1,
130 clone CBRM1/5), anti-CD38 PE (IgG1, clone HB-7), anti-CD36 PE (IgG2a, clone 5-271), from
131 BioLegend, and anti-CD220 PE (IgG1, REA260), anti-CD98 PE (IgG1, clone REA387), anti-CD80
132 PE (IgG1, clone REA661), anti-CD86 PE (IgG1, clone REA968), anti-CD64 PE (IgG1, clone
133 REA978), anti-CD163 PE (IgG1, clone REA812), anti-CD192 (CCR2) PE (IgG1, clone REA264),
134 and anti-CX₃CR1 PE (IgG1, clone REA385) from Miltenyi Biotec.

135

136 CD4+ T cells were identified using anti-CD3 VioBlue® (IgG1, REA613) and anti-CD4 VioGreen™
137 (IgG1, REA623). CD4+ T cell subsets were then further analysed by chemokine receptor
138 expression to define Th subsets (reference) using anti-CD194 (CCR4) APC (IgG1, REA279), anti-
139 CD196 (CCR6) PE-Vio® 615 (IgG1, REA190), anti-CD183 (CXCR3) VioBright™ FITC (IgG1,
140 REA232) and anti-CCR10 PE (IgG1, REA326), all of which were from Miltenyi Biotec.

141

142 **Statistics**

143 The data sets were first tested for normality using the Kolmogorov-Smirnov (K-S) one sample
144 test, where a significant p value <0.05 indicated significant deviation from normality.

145 Depending on if the data reported as parametric or non-parametric, a Pearson or Spearman
146 correlation test was used respectively. The r values are reported to indicate direction
147 (negative values a downward trend; positive values upward trend) and weight of correlation,
148 and a p value <0.05 determined the r value to be significant.

149

150 **Results**

151 *Leptin and IL-6 levels are directly correlated to increasing BMI at 28 weeks of pregnancy.* To
152 evaluate systemic inflammation at 28 weeks of pregnancy in this population of fasted, GDM-
153 negative women of varying pre-pregnancy BMI (n=80) we measured key inflammatory
154 mediators present in plasma. Plasma rather than serum was chosen for analysis as this
155 reflects the liquid phase of blood as it circulates in the body rather than after clotting has
156 occurred. Leptin and IL-6 had a significant positive correlation with BMI (Figure 1A), as
157 described previously ¹¹, and we are the first to show that MCP-1 increases with BMI in
158 pregnant women (Figure 1A) in keeping with the same relationship in not pregnant adults ³⁴,
159 ³⁵. Insulin, cortisol PAI-1, TNF α and IL-8 did not vary with BMI (Figure 1A).

160

161 *Circulating leukocyte numbers are altered with increasing maternal BMI.* Whilst obesity in
162 general is associated with increased levels of neutrophils ³⁶, B cells ³⁷ and non-classical
163 monocytes ²⁰ but decreased levels of eosinophils ³⁸, NK cells ²⁶, and NKT cells ³⁹, little is known
164 about the effects on circulating leukocyte numbers in obese pregnant women. Using flow
165 cytometry, we observed several changes in key blood immune cell populations
166 (Supplementary Figure 1). Increasing BMI was associated with a decrease in the intermediate
167 subset of monocytes (**Error! Reference source not found.**). BMI did not have any effect on
168 the total T cell number, however, increasing BMI was correlated with an increasing CD4:CD8

169 ratio directly attributable to a significant increase in CD4+ T cells accompanied by a significant
170 decrease in CD8+ T cells (**Error! Reference source not found.**). This decline in CD8+ T cells is
171 in keeping with studies in both pregnant women ²⁹ and the general population ²⁸ with obesity.
172 From animal studies it has been suggested that this decline in CD8+ T cells in the peripheral
173 blood is attributable to infiltration of CD8+ T cells into adipose tissue that precedes
174 macrophage accumulation ²⁸. Whilst other studies also have shown a reduction in the
175 proportion of CD3⁺/CD8⁺ T cells in pregnancies with obesity ²⁹, the question as to whether
176 they have accumulated in the adipose tissue remains unanswered. NKT cells also showed a
177 decrease with increasing BMI (**Error! Reference source not found.**) which is also in keeping
178 with observations in the general population ³⁹ and in pregnancy ²⁹. While neutrophils tended
179 to increase with BMI and eosinophils tended to decrease with BMI this was not significant;
180 other populations did not show any differences with maternal BMI.

181

182 *LPS-stimulated cytokine production is unchanged with maternal obesity.* Having confirmed
183 systemic inflammation occurs with increasing BMI in pregnant women (Figure 1) and that
184 there are differences in the relative abundance of some peripheral blood leukocytes with
185 changing BMI in pregnancy (**Error! Reference source not found.**) we next considered whether
186 the inflammatory response of blood mononuclear cells (MNCs) might differ with BMI. MNCs
187 were isolated and then challenged with LPS as a prototypic inflammatory stimulus with
188 thirteen cytokines (IL-1 β , IFN α 2, IFN γ , TNF α , MCP-1, IL-6, IL-8, IL-10, IL-12p70, IL-17A, IL-18,
189 IL-23 and IL-33) measured using a multiplex approach. IL-17A was not detectable in any
190 sample and there was no correlation between the LPS-induced levels of any of the other
191 cytokines and maternal BMI (Figure 3).

192

193 *Monocytes have an adapted phenotype in response to obesity at 28 weeks of gestation.* Given
194 the decline in intermediate monocytes with BMI and the well-recognised role of mononuclear
195 phagocytes in obesity-associated inflammation^{20, 21}, we used flow cytometry to further
196 phenotype the classical (CD14⁺⁺CD16⁻), intermediate (CD14⁺⁺CD16⁺) and non-classical
197 (CD14⁺CD16⁺⁺) subsets of monocytes (see Supplementary Figure 2). The markers chosen for
198 study were those commonly used for phenotyping monocytes linked to various effector
199 functions (CD11b, CD64, CD80, CD86 and CD163), chemokine receptors (CCR2 and CX3CR1)
200 and metabolism associated transporters and receptors (CD36, CD38, CD98 and CD220)
201 including mitochondria. Examples of the histograms of these markers for each subset can be
202 visualised in Figure 4A.

203

204 CD163 (haemoglobin scavenger receptor) expression was increased in intermediate and non-
205 classical monocytes with increasing maternal BMI (Figure 4B). Several studies have shown a
206 correlation between soluble CD163 and BMI which might act as an indicator for risk of insulin
207 resistance⁴⁰. Except for decreased expression of the co-stimulatory molecule CD86 on
208 intermediate monocytes the other markers in this group (CD64 Fcγ receptor 1, CD11b
209 activation marker, CD80 costimulatory molecules) were unchanged (Figure 4B).

210

211 Both CCR2 and CX3CR1 are commonly studied in obesity²¹ and are also differentially
212 expressed on monocyte subsets, i.e., classical monocytes are CCR2^{high}CX3CR1^{low},
213 intermediates CCR2^{high}CX3CR1^{high}, and non-classical CCR2^{low}CX3CR1^{high}. While CX3CR1 did not
214 differ on any of the monocyte subsets with maternal obesity (Figure 4C), CCR2 expression on
215 all subsets of monocytes was elevated with increasing BMI (Figure 4C). Combined with MCP-
216 1 levels that also increased with BMI (Figure 1A) this suggests that the CCL2/CCR2 axis that

217 contributes to obesity related inflammation in the general population is likely also activated
218 in pregnant women with obesity and warrants further investigation.

219

220 With growing interest in the role of immunometabolism in determining cell fate and function
221 we also considered the expression of key metabolic transporters CD36 (fatty acid
222 translocator), CD98 (long-chain neutral amino acid transporter) and CD220 (insulin receptor);
223 we also quantified mitochondrial content (MitoTracker GreenTM). No differences were found
224 in the CD36, CD98 or insulin receptor with increasing BMI (Figure 4D). However, all three
225 subsets of monocytes had decreased mitochondrial content as BMI increased. While deficient
226 and dysfunctional mitochondria have been linked with obesity ⁴¹, we are the first to show this
227 occurs in pregnancies with obesity and in leukocytes specifically. CD38 (cyclic ADP ribose
228 hydrolase that metabolises NAD⁺) has been suggested to play a vital role in pregnancy and
229 here we show on classical and intermediate monocytes at 28 weeks of gestation that CD38
230 expression was significantly decreased with increasing BMI (Figure 4D).

231

232 *Cellular metabolism is not altered by maternal BMI.* Given decreased mitochondrial content
233 was common to all monocyte subsets (Figure 4C) and adipocytes in obesity have shown
234 downregulated OXPHOS proteins, lowered mitochondrial oxidative capabilities and reduced
235 mitochondrial biogenesis ⁴² we then considered whether OXPHOS might be altered with
236 increasing BMI. Summary data for oxidative phosphorylation as oxygen consumption rate
237 (OCR) and glycolysis as extracellular acidification rate (ECAR) are shown as grouped BMIs (BMI
238 ≤ 29.9 versus BMI ≥ 30 ; Figure 5A). OXPHOS and glycolysis parameters were calculated (ATP
239 production, bioenergetic scope, bioenergetic capacity, glycolytic index, supply flexibility
240 index, spare respiratory capacity) and compared by BMI (Figure 5B). There were no significant

241 differences in any OXPHOS or glycolysis parameters with BMI at 28 weeks of gestation. MNCs
242 in pregnancy at term have previously been found to have decreased basal glycolysis and
243 glycolytic capacity in conjunction with increased bioenergetic health index ³³. Very little
244 otherwise is known about specific immune cell bioenergetics in obesity or pregnancy.

245

246 *Pregnant women with obesity show altered Th1/Th2/Th17.* Given the dramatic effect of
247 maternal obesity on T cell numbers (Figure 1) and the role of immune plasticity related to
248 Th1/Th2/Th17 in pregnancy success ⁴³ we also considered the effect of BMI on CD4+ T cell
249 subsets. The relative abundance of different Th subsets was determined based on their
250 chemokine expression profile – CXCR3, CX3CR1, CCR4, CCR6 and CCR10 - to identify Th1
251 (CXCR3-CCR4-CCR10-CCR6-), Th2 (CXCR3-CCR4+CCR10-CCR6-), Th9 (CCR4-CCR6+), Th17
252 (CXCR3-CCR4+CCR10-CCR6+), Th17/1 (CXCR3-CCR4-CCR10-CCR6+) and Th22
253 (CCR4+CCR6+CCR10+CXCR3-) subsets ⁴⁴ (Figure 6A). The percentage of Th2 cells as well as
254 closely related Th9 cells decreased with increasing maternal BMI (Figure 6B) but other subsets
255 were unaffected. When we examined the cytokine profile induced in response to the TCR
256 activator CytoStimTM and measured using a multiplex approach, we found that IL-4 production
257 was also decreased with increasing BMI (Figure 6C). This decrease in IL-4 was accompanied
258 by increases in IL-6, IL-17A, IL-17F and IL-22 (Figure 6C). Overall, this suggests a decrease in
259 Th2 accompanied by an increase in Th17 that could underpin adverse obstetric outcomes in
260 pregnant women with obesity.

261

262

263 **Discussion**

264 Using a cohort of women of varying BMI but of very similar gestation and confirmed as
265 negative for GDM by glucose tolerance testing, in contrast to many other studies of obesity
266 in pregnancy, we have been able to establish the effects of obesity on systemic maternal
267 immunity early in the third trimester. We confirm that maternal obesity is associated with
268 systemic inflammation and monocyte activation and extend this to suggest activation of the
269 CCL2/CCR2 axis, as in the general population, with obesity. We also show a profound effect
270 of increasing BMI on loss of mitochondrial content; while this did not seem to affect oxidative
271 phosphorylation capacity this measure was made on total mononuclear cells rather than
272 isolated monocytes as would have been ideal. Finally, using both phenotypic and functional
273 analysis we show for the first time that maternal obesity causes downregulation of Th2 cells
274 and responses favouring heightened Th17 in particular.

275

276 Increased leptin and IL-6 in pregnant women with obesity has been described previously ¹¹
277 and we extend this phenotype of systemic inflammation to include CCL2/MCP-1. Importantly,
278 we confirm increasing leptin with increasing maternal BMI in a cohort that does not include
279 women with either current or a history of hyperglycaemia and/or GDM/T2DM. Together with
280 Wang et al ⁴³, we support that this relationship likely occurs throughout pregnancy. Similarly,
281 we confirm systemic elevation of IL-6 but not TNF with increasing maternal BMI ¹¹. While
282 CCL2/MCP-1, a pro-inflammatory chemokine, is reported to be decreased in healthy
283 pregnancy ⁴⁵, herein obesity in pregnant women was associated with increased CCL2/MCP-1
284 as has been observed in the general population ¹⁵. Given maternal CCL2/MCP-1 levels have
285 been suggested to be a marker of labour ⁴⁵, levels with maternal obesity could contribute to
286 increased risk of early labour or miscarriage ⁴⁶. Combined with our observation of elevated
287 CCR2 on all monocyte subsets with increasing maternal BMI, as in the general population ²¹,

288 it is likely that the CCL2/CCR2 axis is also active in pregnant women and manifests as increased
289 intrinsic migratory capacity of monocytes but this remains to be formally investigated. The
290 suspected increased intrinsic migratory capacity of monocytes in pregnancies with obesity
291 would suggest altered macrophage phenotype in adipose and placental tissue. Macrophages
292 have been reported to accumulate in the placenta of pregnant women with obesity ¹¹ but
293 whether this is CCL2/CCR2 mediated recruitment of maternal monocytes remains to be
294 determined.

295

296 The many obesity-associated changes in monocytes prompted our closer scrutiny of this
297 population. In contrast to the increase in the non-classical subpopulation seen in the general
298 population ²⁰, we observed diminished intermediate monocytes with increasing maternal
299 BMI. Other highlights of the effect of increasing maternal BMI include changes in CD163, CD86
300 and CD38 which are all novel findings for maternal obesity. An increased expression of CD163
301 is typical of monocytes and macrophages in response to inflammation ⁴⁷ and was seen on
302 intermediate and non-classical monocytes with increasing maternal BMI. We did not
303 measure soluble CD163 but this is elevated in sepsis ⁴⁸ and other inflammatory conditions and
304 would be worth considering in further studies. CD86 was decreased with increasing maternal
305 BMI on intermediate monocytes – in contrast to the general population, where CD86
306 expression has been found to be elevated on non-classical monocytes in obesity ⁴⁹. CD38
307 expression on monocytes and macrophages is induced in inflammatory conditions ⁵⁰ and a
308 decrease in the expression of CD38 correlates with suppression of adipogenesis and
309 lipogenesis in adipose tissue in mouse models ⁵¹. Our data shows a decrease in CD38
310 expression on classical and intermediate monocytes suggesting that the monocytes might be
311 attempting to counter the exacerbated inflammatory state of maternal obesity. CD38 also has

312 a role in metabolism, with the ability to produce cyclic ADP-ribose and nicotinic acid adenine
313 dinucleotide phosphate (NAADP) from NAD⁺ and NADP⁺ respectively. Inhibitors of CD38,
314 such as the flavonoid apigenin from foods such as parsley, have shown beneficial effects in
315 tackling obesity in animal models ⁵². In these models elevated cellular levels of NAD⁺ are
316 beneficial, and CD38 knockout increases the NAD⁺ levels and protects against obesity ⁵².

317

318 Metabolically, while our data on fatty acid and amino acid transporters revealed no
319 differences related to maternal BMI, all three subsets of monocytes had reduced
320 mitochondrial content suggesting that monocyte metabolism – especially OXPHOS - is
321 compromised in maternal obesity. Therefore, we also considered the bioenergetic
322 capabilities of MNCs. It would have been ideal to undertake this analysis on isolated
323 monocytes to better match the flow cytometry finding but this was not possible – this was a
324 study of MNCs and only flow cytometry allowed delineation of effects of maternal obesity on
325 discrete cell types within this heterogenous mix. There appears to be very little research
326 surrounding specific immune cell bioenergetics in obesity or pregnancy although the spare
327 respiratory capacity of monocytes has been shown to be negatively correlated with
328 percentage body fat ⁵³. A study investigating the effect of the bioenergetic function of
329 peripheral monocytes in women with HIV illustrated that monocytes of infected women with
330 obesity had impaired bioenergetic health (reduced basal and maximal oxygen consumption
331 rate as well as decreased bioenergetic health index) in comparison to lean infected women
332 ⁵⁴. A recent study by Sureshchandra et al. has shown that at term, monocytes from pregnant
333 women with obesity have reduced ECAR at baseline and following LPS and glucose injections,
334 in comparison to lean pregnant women that might support their maladaptive phenotype ²².
335 There are no other studies of the effects of obesity on the bioenergetic profile of MNCs in

336 pregnancy or in obesity in general. While our results show no effect of maternal BMI, using a
337 similar approach we have seen that MNCs of pregnant women with GDM have reduced
338 oxidative phosphorylation compared to their GDM-negative counterparts (unpublished data).
339 Given the absence of any difference in cellular bioenergetics with maternal obesity it is
340 perhaps not surprising that we did not see any difference in LPS-stimulated cytokine
341 production despite differences in such responses in the general population with obesity such
342 as increased production of IL-1 β and RANTES upon LPS stimulation of classical monocytes²¹
343 and heightened LPS-stimulated TNF, IL-2, and IFN γ and decreased IL-10 production from LPS-
344 stimulated MNCs⁵⁵. However, cytokine production by monocytes is underpinned by glycolysis
345⁵⁶ which does not depend on mitochondria and was also unchanged with maternal BMI. It
346 would be worthwhile investigating the effects of maternal BMI on monocyte effector
347 functions supported by the mitochondria including ROS production and fatty acid oxidation.
348 All of this does suggest however that it is vital to further investigate phenotypic and functional
349 adaptation of monocytes to both obesity and GDM. This is especially so as pregnancy-
350 associated monocyte activation is exacerbated in for example preeclampsia²⁴, and obesity is
351 a risk factor for preeclampsia²⁵.

352

353 Monocytes are not the only cell type affected by maternal obesity. The immunophenotyping
354 performed on MNCs revealed that T cells are particularly susceptible to the effects of
355 maternal BMI. As already reported²⁹, we too found a negative correlation between maternal
356 obesity and the abundance of iNKT cells. In the general population, iNKT cells are depleted in
357 adipose tissue of people with obesity⁴¹ and the addition of iNKT cells resolves increased body
358 fat, leptin and insulin sensitivity³⁹. For conventional T cells, there was no change in total T
359 cells but there was a significant increase in CD4+ T cells accompanied by a decrease in CD8+

OBESITY AND THE MATERNAL IMMUNE SYSTEM

360 T cells which significantly impacted the CD4:CD8 T cell ratio. This decline in peripheral CD8+
361 T cell counts with obesity in both the general population ²⁸ and in pregnant women ²⁹ appears
362 to be a common finding. While animal studies suggest that this might be explained by the
363 accumulation of CD8+ T cells in adipose tissue ²⁸, little is known about the effects of pregnancy
364 - either with or without obesity - on adipose tissue immune profiles. While there are recent
365 studies exploring the impact of obesity on adipocyte hypertrophy and adipose tissue
366 macrophage populations in visceral adipose tissue from pregnant women with and without
367 obesity ⁵⁷ there are few studies of the effects of maternal obesity on adipose tissue with most
368 focusing on GDM ⁵⁸. Our and other findings in changes to the abundance of some circulating
369 immune cell populations certainly warrant further effort to understand what is happening
370 within adipose tissues in pregnancy and the interrelationship of blood, adipose tissue and
371 placenta. It also is unfortunate that we did not include regulatory T cells in our analysis but
372 clearly investigation of these and other important minor cell subsets such as ILCs and MAIT
373 cells is needed.

374

375 The effect of maternal BMI on the relative abundance of CD4 and CD8 T cells, combined with
376 the recognised importance of the Th1/Th2/Th17/Treg axis in pregnancy success ⁵⁹ prompted
377 us to consider the impact of obesity on this phenotype. Using a flow cytometry based
378 approach based on patterns of chemokine expression by CD4+ T cells ⁴⁴ we found that
379 maternal obesity was associated with a decline in Th2 and Th9 cells. This decline in Th2 cells
380 was accompanied by decreased production of IL-4 upon stimulation of MNCs revealing a
381 negative effect of maternal obesity on Th2 responsiveness in particular. This appears to be
382 accompanied by increased Th1 and Th17 cytokine production suggesting disruption of the
383 Th1/Th2/Th17 axis in pregnant women with obesity. Our findings are consistent with the

384 obesity-associated shift to Th1 and Th17 in the general population ^{30, 60}. In the setting of
385 pregnancy such a shift could lead to recurrent pregnancy loss ⁶¹ and pre-term birth ⁶² for
386 which obesity is a recognised risk factor. Obesity also has been shown to be an indicator for
387 severity of COVID-19 symptoms ¹⁰ including in pregnancy ⁶³ and the altered Th1/Th2/Th17
388 profile shown here could account for this obesity-associated increased risk of severe disease
389 in pregnant women.

390

391 **Conclusions**

392 BMI is strongly correlated to several differences in pregnant woman at 28 weeks of gestation.
393 These changes offer explanations for increased risk of adverse obstetric outcomes, and some
394 may offer targets for therapy. Further investigation into isolated cell populations as well as
395 adipose tissue and placenta is required to further our understanding of the influence of
396 obesity on pregnancy outcome.

590

591 **Table 1. Summary data for study participants.** All women were GDM-negative on oral glucose tolerance test the only
 592 significant difference between the lean/overweight (BMI ≤ 29.9) and obese/morbidly obese (BMI ≥ 30.0) groups was BMI.

593

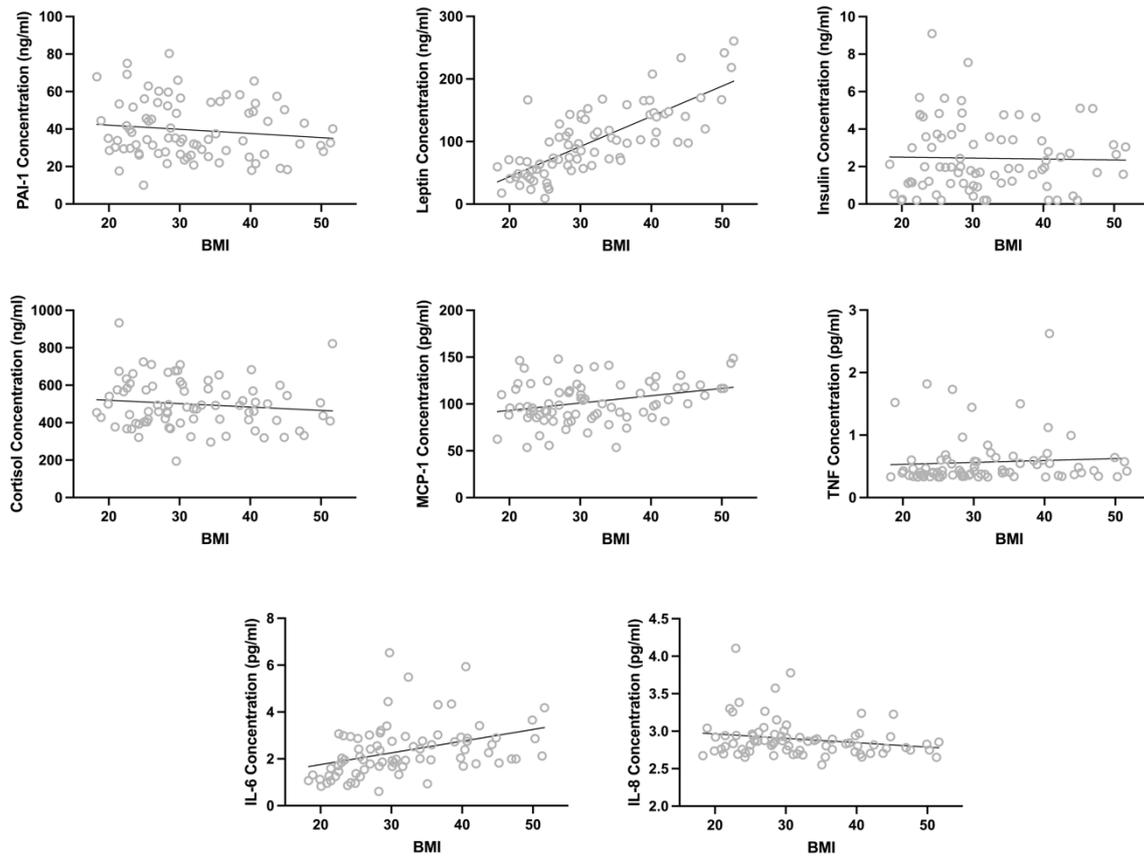

Figure 1: Plasma levels of inflammatory mediators in GDM-negative women of varying pre-pregnant BMI at 28 weeks of gestation. Plasma was available from fasted pregnant women of approximately 28 weeks of gestation (n=80) and was used for analysis as described in the Materials and Methods and correlated to BMI. Statistics were determined using either a Pearson r or Spearman r test dependent on their K-S test result, where $p < 0.05$ was determined significant. Analytes measured were: PAI-1 ($r = -0.1242$; $p = 0.2722$), leptin ($r = 0.7635$; $p < 0.0001$), insulin ($r = 0.0017$; $p = 0.9882$), cortisol ($r = -0.1196$; $p = 0.2937$), MCP-1 ($r = 0.3024$; $p = 0.0064$), TNF ($r = 0.1931$; $p = 0.0861$), IL-6 ($r = 0.4895$; $p < 0.0001$) and IL-8 ($r = -0.1923$; $p = 0.0875$).

595

596

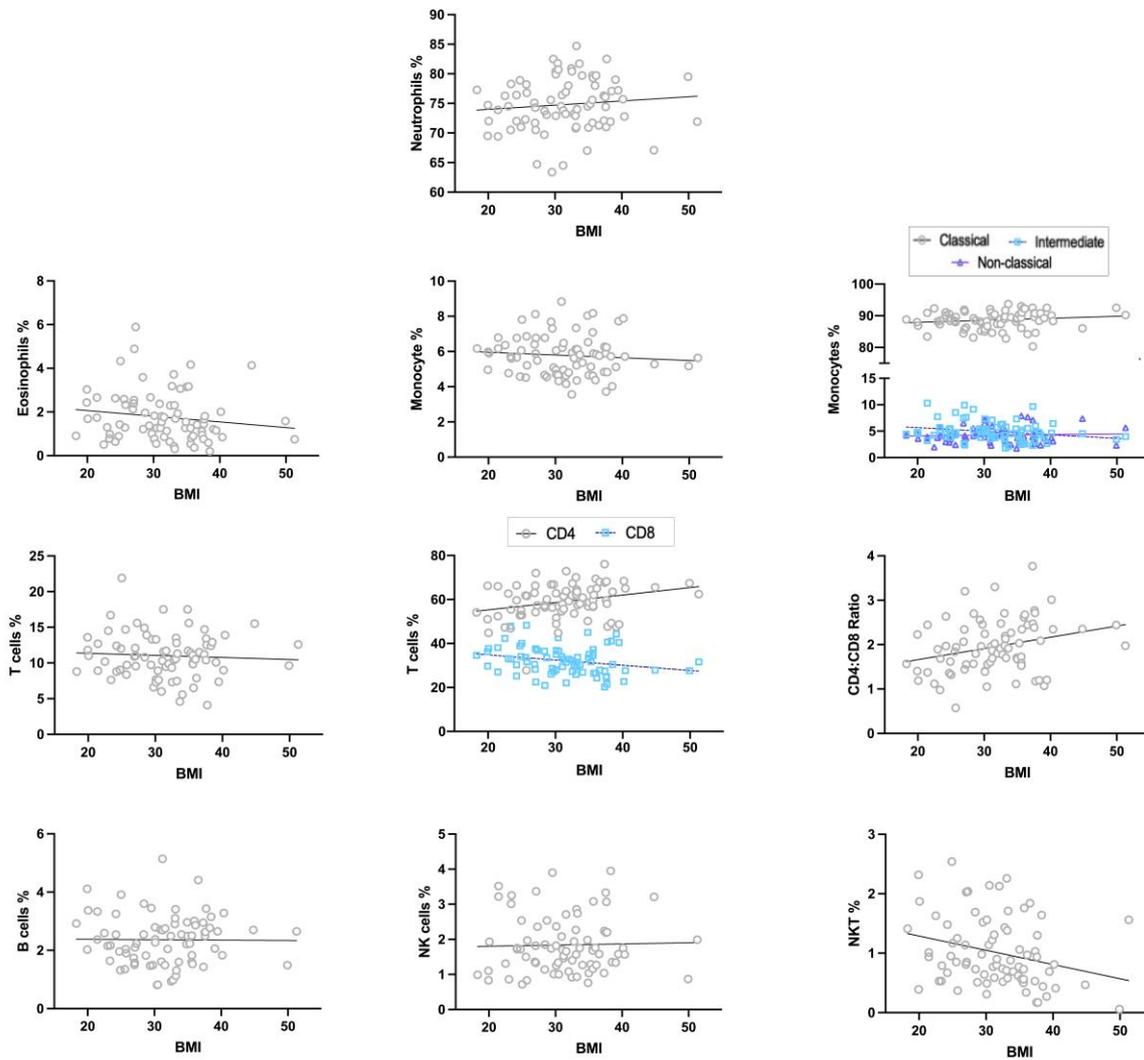

Figure 2: The impact of BMI on leukocyte populations in pregnancy. Whole blood (n=77) from fasted pregnant women of approximately 28 weeks of gestation was used for leukocyte phenotyping as described in the materials and methods. They were correlated to BMI. Statistics were determined using either a Pearson r or Spearman r test dependent on their K-S test result, where $p < 0.05$ was determined significant. Leukocyte populations which were determined where: neutrophils ($r = 0.1053$; $p = 0.3654$), eosinophils ($r = -0.2034$; $p = 0.0760$), total monocytes ($r = -0.898$; $p = 0.4375$), classical monocytes ($r = 0.2138$; $p = 0.0637$), intermediate monocytes ($r = -0.2394$; $p = 0.0372$), non-classical monocytes ($r = -0.0354$; $p = 0.7614$), total T cells ($r = -0.0606$; $p = 0.6004$), CD4 T cells ($r = 0.2798$; $p = 0.0137$), CD8 T cells ($r = -0.2476$; $p = 0.0299$), CD4:CD8 ratio ($r = 0.2789$; $p = 0.0140$), B cells ($r = -0.0105$; $p = 0.9276$), NK cells ($r = 0.0628$; $p = 0.5877$) and NKT cells ($r = -0.2842$; $p = 0.0123$).

597

598

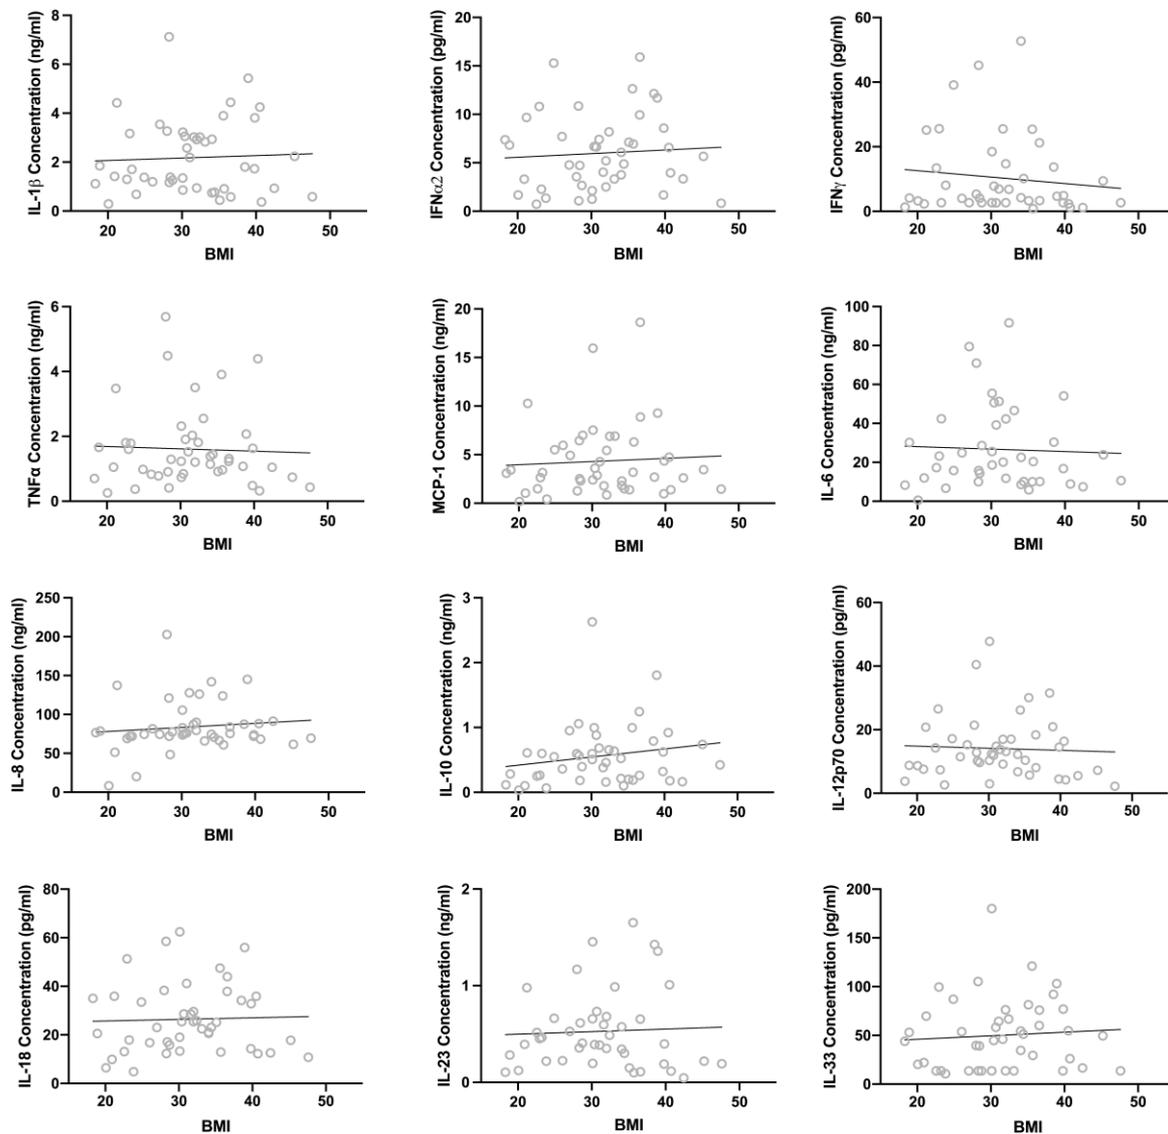

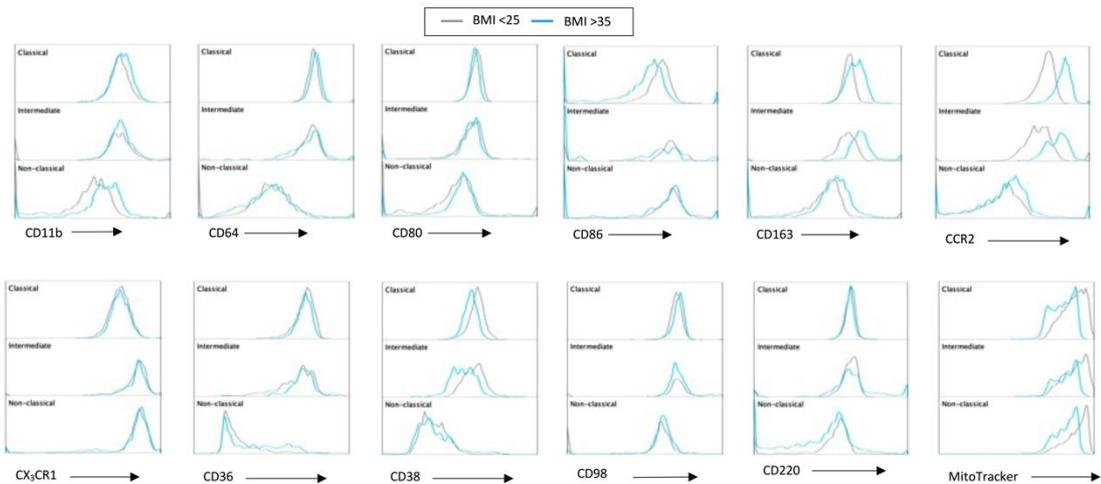

Figure 3: LPS-stimulated cytokine production by peripheral blood mononuclear cells from GDM-negative women of varying pre-pregnant BMI at 28 weeks of gestation. MNCs (n=45) were stimulated with LPS and then levels of cytokines (ng/ml or pg/ml) measured using a multiplex bead array for flow cytometry. Statistics were determined using either a Pearson r or Spearman r test dependent on their K-S test result, where $p < 0.05$ was determined significant. IL-17A was not detectable and there was no significant correlation between BMI and any of the other cytokines measured: IL-1 β ($r = -0.0040$; $p = 0.9791$), IFN $\alpha 2$ ($r = 0.0687$; $p = 0.6579$), IFN γ ($r = -0.1182$; $p = 0.4503$), TNF ($r = -0.0144$; $p = 0.9254$), MCP-1 ($r = 0.0651$; $p = 0.6710$), IL-6 ($r = -0.0602$; $p = 0.7085$), IL-8 ($r = 0.0083$; $p = 0.5642$), IL-10 ($r = 0.2085$; $p = 0.1694$), IL-12p70 ($r = -0.0596$; $p = 0.6972$), IL-18 ($r = 0.0331$; $p = 0.8290$), IL-23 ($r = -0.0791$; $p = 0.6099$) and IL-33 ($r = 0.1555$; $p = 0.3078$).

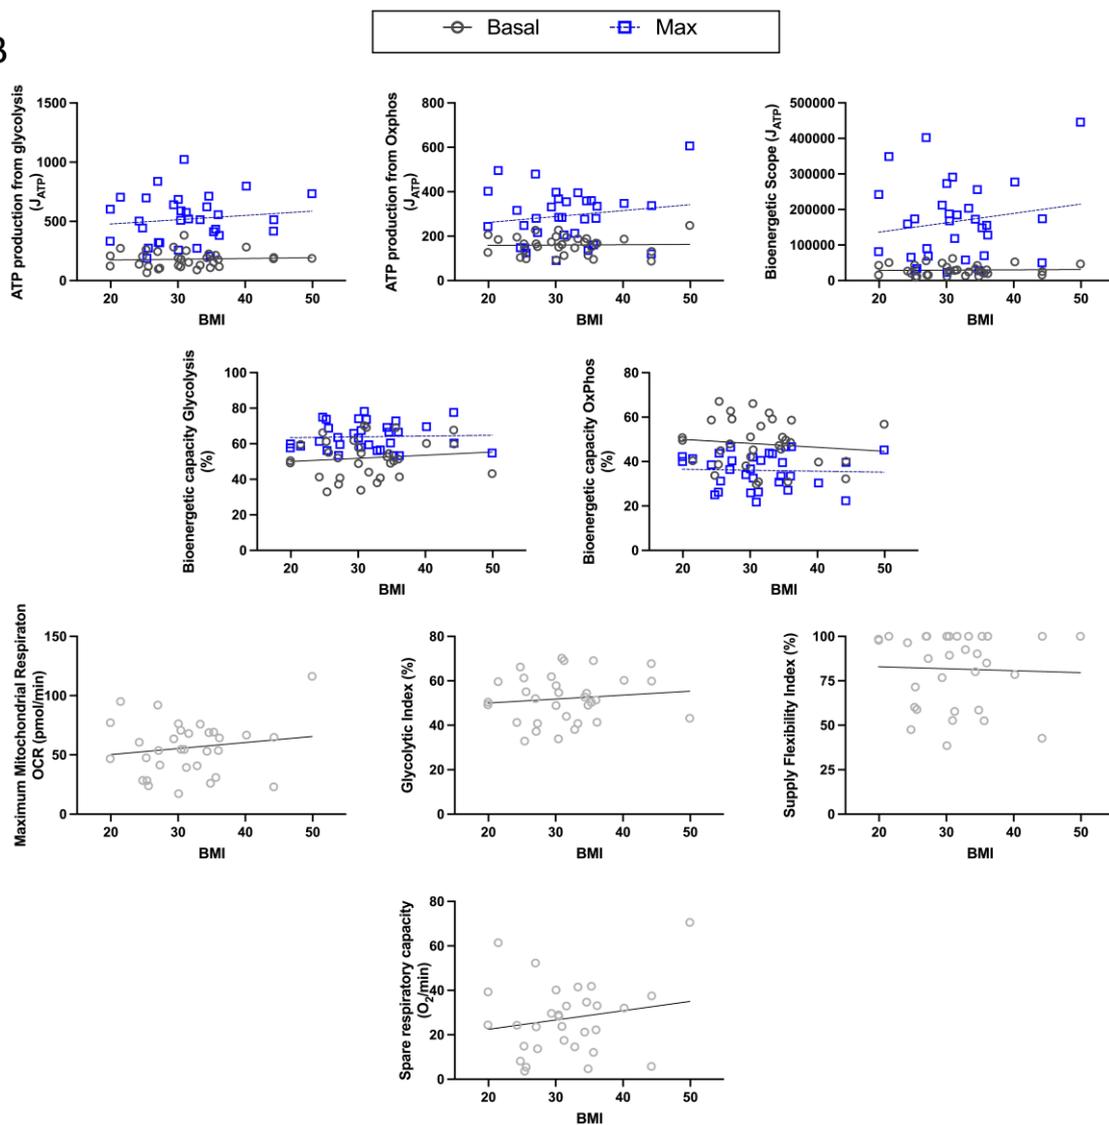

Figure 5: The bioenergetic capacity of mononuclear cells from GDM-negative women of varying pre-pregnant BMI at 28 weeks of gestation. OCR and ECAR of MNCs from pregnant women at approximately 28 weeks ($n=32$) were measured using the Seahorse extracellular flux analyser as described in the Materials and Methods and correlated to maternal obesity. **(A)** The trace of OCR and ECAR against time for grouped not-obese vs obese. **(B)** Specific glycolytic or oxidative phosphorylation parameters were extracted and correlated against BMI. Statistics were determined using either a Pearson r or Spearman r test dependent on their K-S test result, where $p < 0.05$ was determined significant. These parameters included: ATP production from glycolysis (basal $r = 0.0650$, $p = 0.7239$; max $r = 0.1268$, $p = 0.4894$) and OXPHOS (basal $r = 0.0226$, $p = 0.9025$; max $r = 0.1549$, $p = 0.3972$), bioenergetic scope (basal $r = 0.0386$, $p = 0.8339$; max $r = 0.1668$, $p = 0.3617$), bioenergetic capacity for glycolysis (basal $r = 0.1155$, $p = 0.5289$; max $r = 0.0405$, $p = 0.8259$) and OXPHOS (basal $r = -0.1155$, $p = 0.5289$; max $r = -0.0405$, $p = 0.8259$), maximum mitochondrial respiration ($r = 0.1549$; $p = 0.3972$), supply flexibility index ($r = 0.0168$; $p = 0.9271$), glycolytic index ($r = 0.1156$; $p = 0.5288$) and spare respiratory capacity ($r = 0.1814$; $p = 0.3286$).

OBESITY AND THE MATERNAL IMMUNE SYSTEM

606
607
608

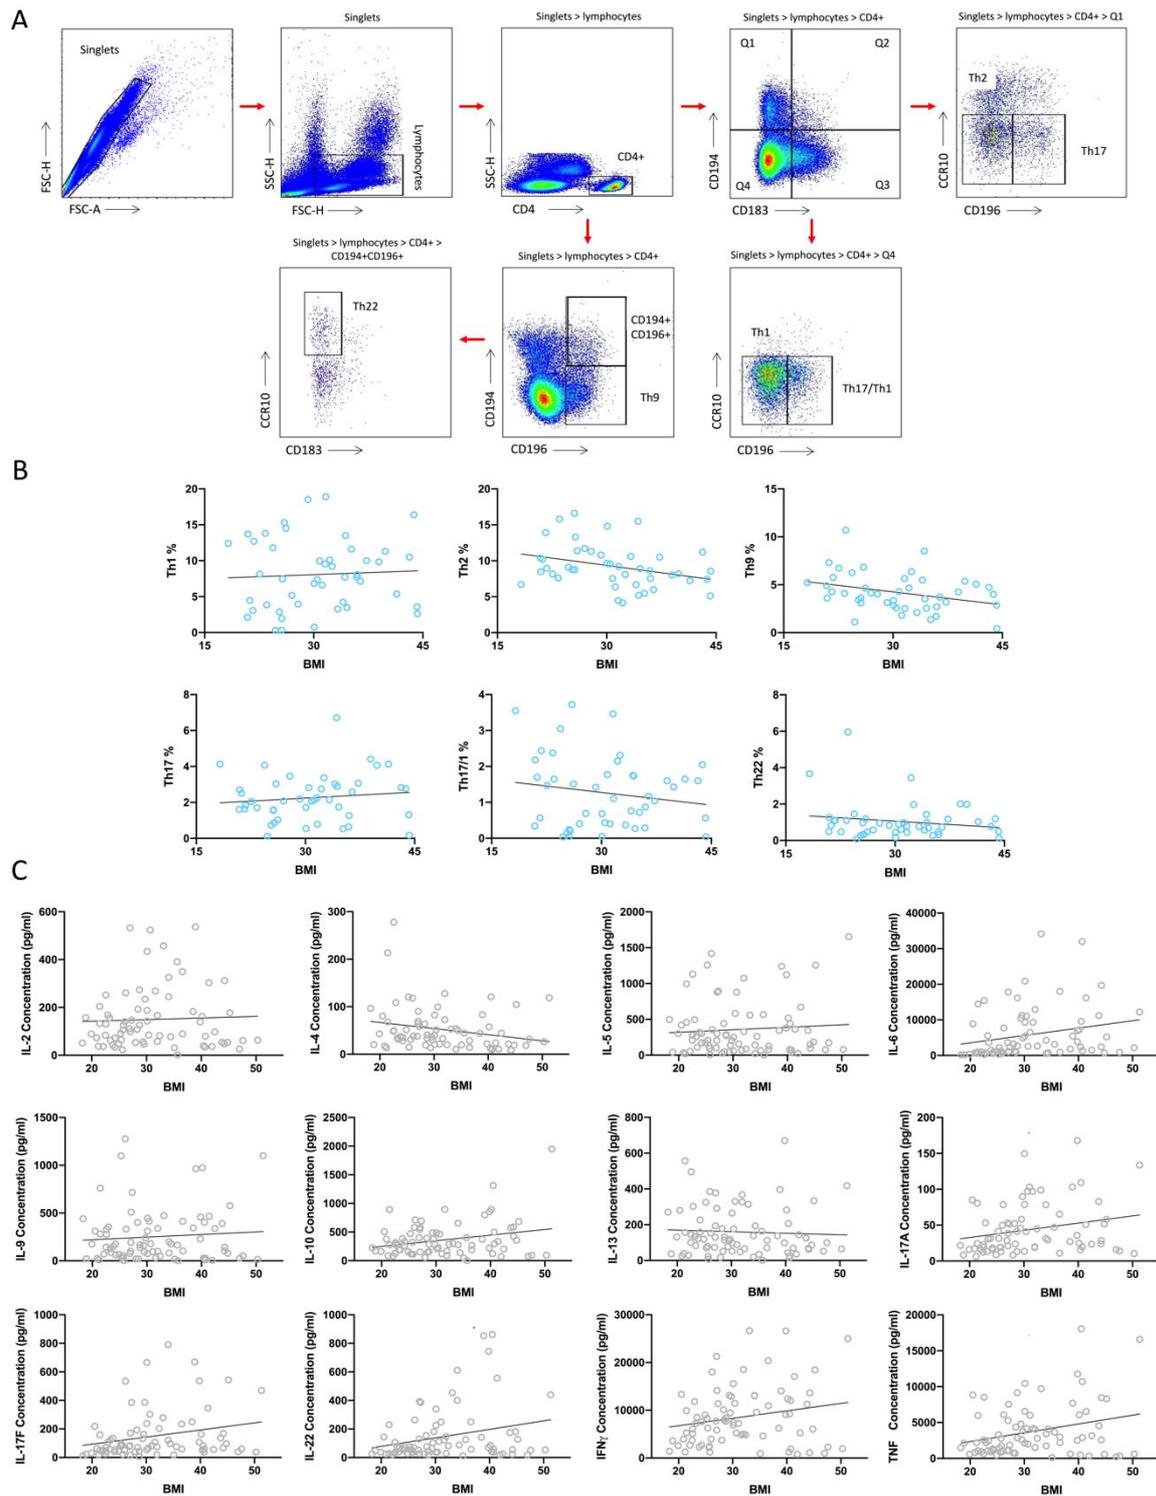

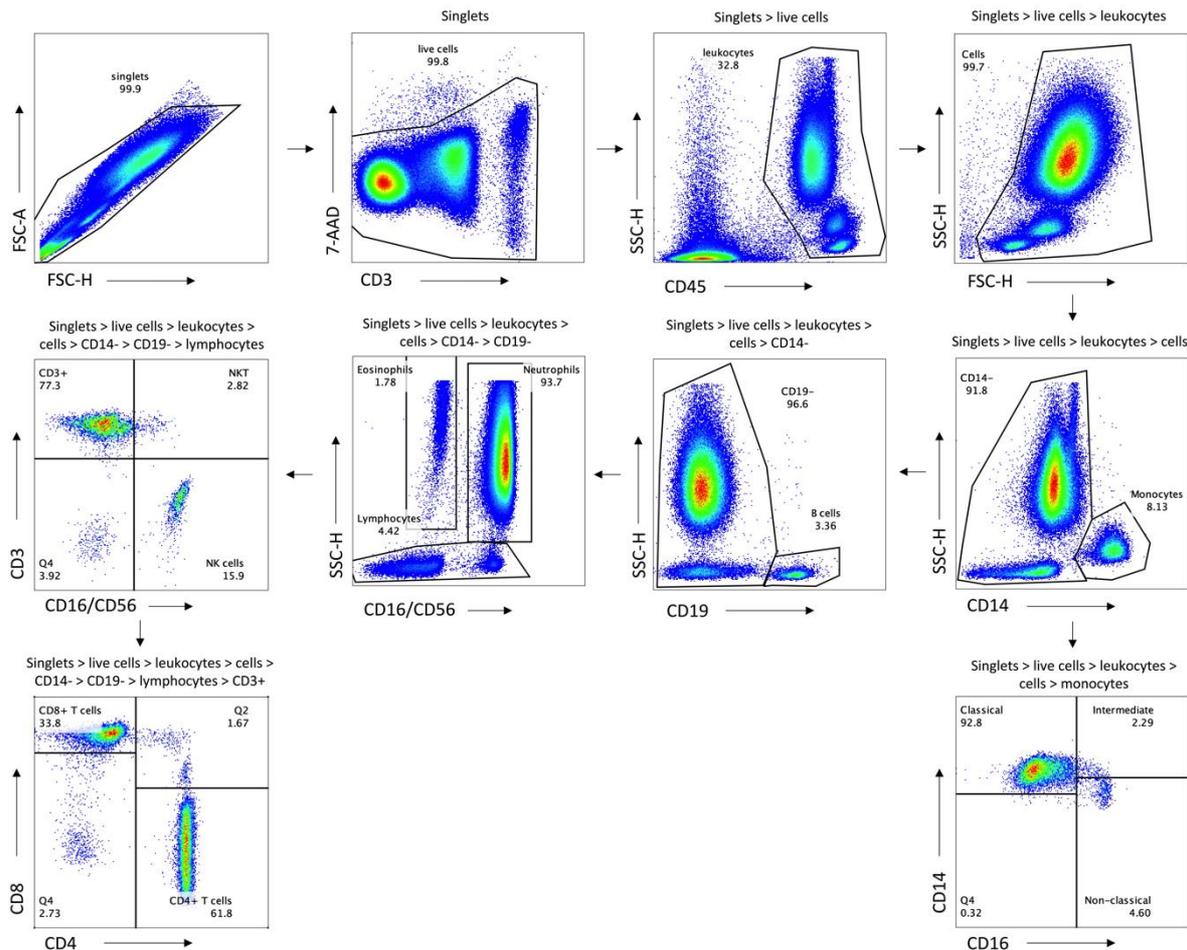

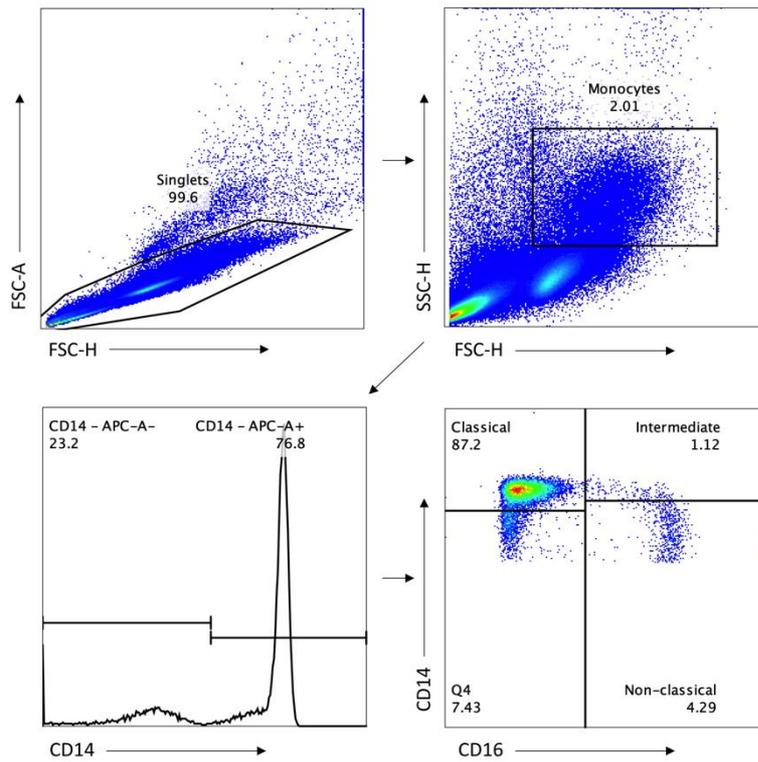

Figure 6: The Th profile of GDM-negative women of varying pre-pregnant BMI at 28 weeks of gestation. (A) Gating strategy for identifying the Th subsets using flow cytometry and chemokine receptor profile – CCR4-CXCR3-CCR10-CCR6- Th1; CCR4-CXCR3-CCR10-CCR6- Th2; CCR4-CCR6+ Th9; CCR4-CXCR3-CCR10-CCR6+ Th17; CCR4-CXCR3-CCR10-CCR6+ Th17/1; CCR4-CCR6+ CCR10+ Th22. Statistics were determined using either a Pearson r or Spearman r test dependent on their K-S test result, where $p < 0.05$ was determined significant. **(B; blue)** The populations identified were (n=46): Th1 ($r = 0.0538$; $p = 0.7225$), Th2 ($r = -0.3202$; $p = 0.0341$), Th9 ($r = -0.3205$; $p = 0.0319$), Th17 ($r = 0.1202$; $p = 0.4315$), Th17/1 ($r = -0.1662$; $p = 0.2696$) and Th22 ($r = -0.0705$; $p = 0.6415$). **(C; grey)** Multiplex analysis of cytokines from CytoStim™-stimulated MNCs (n=74): IL-2 ($r = 0.0295$; $p = 0.8046$), IL-4 ($r = -0.2806$; $p = 0.0162$), IL-5 ($r = -0.0158$; $p = 0.8898$), IL-6 ($r = 0.4166$; $p = 0.0002$), IL-9 ($r = 0.0240$; $p = 0.8339$), IL-10 ($r = 0.1193$; $p = 0.2983$), IL-13 ($r = -0.1013$; $p = 0.3745$), IL-17A ($r = 0.2753$; $p = 0.0168$), IL-17F ($r = 0.2973$; $p = 0.0091$), IL-22 ($r = 0.2257$; $p = 0.0484$), IFN γ ($r = 0.1762$; $p = 0.1228$) and TNF ($r = 0.1979$; $p = 0.0824$).

609
610
611
612

Supplementary Figure 1: Gating strategy for the 8-colour immunophenotyping. Singlets are first selected via a forward scatter (FSC) height (H) vs area (A). Dead cells (7-AAD positive) are excluded. Only leukocytes (CD45+) are then selected, before debris is removed from the gating strategy on an FSC-H. vs side-scatter (SSC)-H plot. Monocytes are isolated by being CD14+ and further separated into its subsets based on their CD14+ and CD16+ expression. From the CD14-negative cells, B cells (CD19+) are isolated. It is possible to identify eosinophils (CD16/CD56-negative), neutrophils (CD16/CD56-positive) and lymphocytes (low SSC profile). In the lymphocyte profile, T cells (CD3+), NKT cells (CD3+CD16/CD56+) and NK cells (CD3-CD16/CD56+) are identified. T cells can be segregated into by their CD4 and CD8 expression.

613

Supplementary Figure 2: Gating strategy for the selection of monocytes and their subsets in MNCs. Singlets were first selected using a FSC-H vs FSC-A dot plot. Using a FSC-H vs SSC-H dot plot, monocytes were identified according to their relative size and granularity. A histogram visualising the CD14 expression enabled gating on the CD14-positive peak. Monocyte subsets were then identified according to their CD14/CD16 profile.
