PRESENTED AT:

BACKGROUND & OBJECTIVES

Backgrounds:

- Phosphorus (P) export from urban stormwater runoff increases eutrophication risks in receiving water bodies;
- Bioretention cells (**Figure 1**) have emerged as a low impact development (LID) option for reducing runoff P export by soil infiltration;
- Comprehensive mechanistic understanding of P accumulation in bioretention cells is limited.

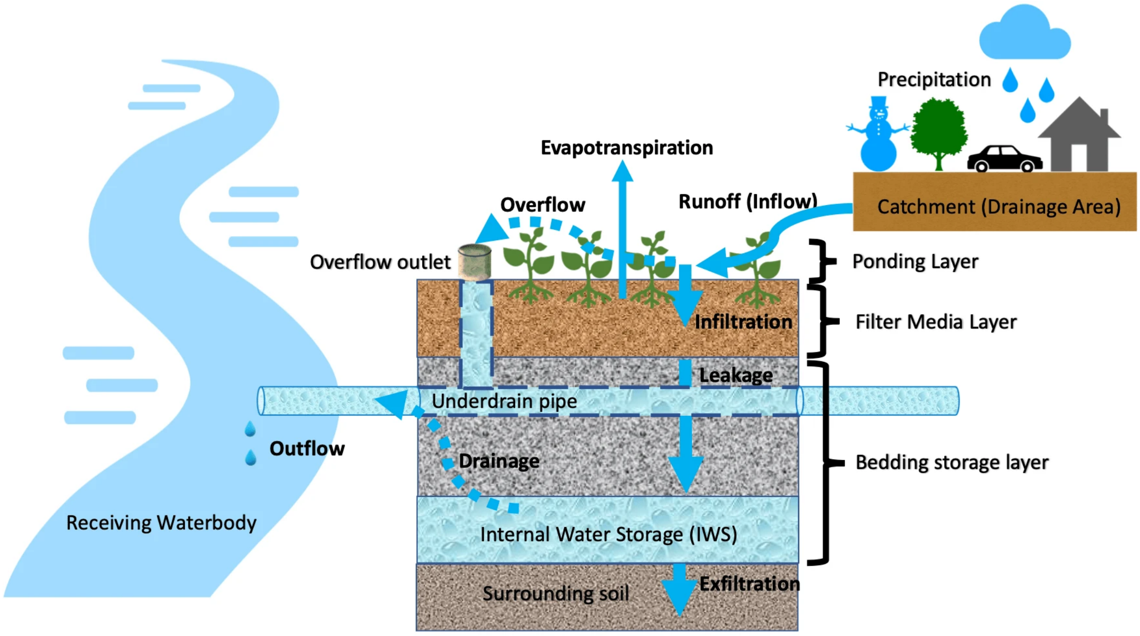

Figure 1. Vertical structure and hydrologic processes of bioretention cell in this study

Objectives:

- Improve understanding of long-term P accumulation mechanisms in bioretention cells;
- Develop a modelling tool that can predict long-term P accumulation in and export from bioretention cell;
- Identify main P sink and critical processes for P retention in bioretention cell.

METHODOLOGY

Field Monitoring:

- Outflow water quantity and quality (including TP and SRP), onsite meteorological data, soil P contents at different depths during 2012 and 2019;
- Soil core samples collected in 2019 was further sequentially extracted to identify under which chemical forms P accumulated in bioretention soil.

Reactive Transport Modelling:

- Bioretention cell is conceptualized as a 3-layer system (**Figure 2**);
- Both hydrologic and P transformation processes inside the bioretention cell are simulated. P transport in filter media is simulated by a 1-D advection-dispersion-reaction model (**Figure 2**);
- Conduct mass balance and sensitivity analysis to identify main P sink and critical processes that control P retention.

CONCLUSIONS & ACKNOWLEDGEMENTS

Conclusions:

- Exfiltration is the major pathway for runoff reduction while accumulation of P in the soil layer is responsible for the majority of P removal in the bioretention cell;
- Importance of processes that control P retention in filter media: filtration > adsorption > precipitation > plant uptake;
- Mineral particulate inorganic P is likely the largest sink for TP retention in bioretention soil;
- Precipitation of P containing minerals and P uptake by plants prevent exhaustion of the P retention capacity in the soil layer.

Future Direction:

- Simplify the model based on critical processes identified in this study for upscaled application;
- Conduct climate change scenarios analysis to understand change of P retention performance of bioretention cell under future climate.

ABSTRACT

Phosphorus (P) concentrations in urban stormwater runoff are typically elevated compared to those associated with runoff from natural lands. Urban P export is a leading driver of eutrophication problems in downstream aquatic systems. Low impact development (LID) options such as bioretention cells (Bio-C) have emerged as a green solution for reducing peak discharge and nutrient export from urban areas. Despite the prevalent implementation of Bio-C worldwide, the mechanistic understanding of P cycling in these systems remains limited. This is especially true in cold climate regions where winter-associated processes can play a crucial role in the performance of Bio-C. We conducted data mining and numerical reactive transport modeling to simulate the fate and transport of P in a monitored Bio-C system in the Toronto metropolitan area, Ontario, Canada. Our aim is to utilize the model for predicting the export fluxes and speciation of P from the Bio-C following precipitation events of variable magnitude and duration. Our model development differs from existing models by the incorporation of a more detailed representation of the biogeochemical processes controlling the reactive transport and speciation of P in the Bio-c system. We employ our model to predict temporal variations in the Bio-C's P retention, outflow and exfiltration. the modeling work is paired with the sequential chemical extraction of P from soil samples taken from the Bio-C to characterize different P pools in the cell media. We then use these data to verify the model predicted P accumulation rates. In ongoing work, we are using the improved predictive understanding of P cycling in the Bio-C to analyze how P retention and export may change under the more hydrologically extreme conditions projected for southern Ontario in the coming decades.
