Contents of this file

Introduction

Text S1 provides additional information on the implementation of melting in our geo-dynamic simulations. Text S2 describes how we calculate element partition coefficients as a function of pressure, temperature and composition. Text S3 describes how we estimate mineral major element compositions for calculating element partition coefficients. Text S4 describes an alternative method for calculating the melt-focusing distance (x_f).

Text S1. Physical Melting Model

Melt fraction as a function of pressure and temperature, $X(P, T)$, is calculated using the equations of Katz, Spiegelmann, and Langmuir (2003). Entropy of fusion, thermal heat capacity, and expansivity of solid peridotite are updated to 407 J kg^{-1} K^{-1}, 1187 J kg^{-1} K^{-1}, and 3×10^{-5} K^{-1}, respectively, in line with additional experimental data (Shorttle et al., 2014). The Katz et al. (2003) melting model contains a number of coefficients which must be parameterized by fitting to peridotite melting experiments. Since we require the mineralogy of the residue to be recorded during these experiments, this physical melting model is constrained using a greater variety of experimental data than we have used to parameterize our geochemical melting model. Therefore, we have chosen to update a number of these constants to increase consistency between the melting model and our restricted database. The melt fraction at which clinopyroxene is exhausted, $X_{cpx-out}$, is a function of the weight fraction of clinopyroxene in the solid peridotite, M_{cpx}, and the reaction coefficient, R_{cpx}, which is a function of pressure, P,

$$\text{i.e., } X_{cpx-out} = \frac{M_{cpx}}{R_{cpx}(P)}, \tag{1}$$

$$\text{where } R_{cpx} = R_1 + R_2 P. \tag{2}$$

Our geochemical melting model is constrained using experiments conducted on MM3 and KR4003 peridotites (Baker & Stolper, 1994; Walter, 1998; Falloon et al., 1999). $X_{cpx-out}$ is predicted to decrease as a function of pressure within the Katz et al. (2003) melting parameterization. However, in these experiments, $X_{cpx-out}$ increases as a function of pressure (Figure S1). Here, we exploit the M_{cpx} and $X_{cpx-out}$ values recorded within these experiments to approximate M_{cpx}, R_1 and R_2 as 0.18, 0.94 and -0.1, respectively. To

provide a good fit for melt fraction as a function of temperature, two additional constants,

β_2 and B_1, are also updated to 1.2 and 1520 °C, respectively (Figure S2).

The decompression melting model parameterised by Katz et al. (2003) assumes that no heat is lost during melting. However, it is necessary to modify these equations in this case since within our geodynamic model we allow heat diffusion to occur. We replace the adiabatic gradient term with the actual temperature gradient that is experienced by each particle in the geodynamic model using Equations 3–5 in the main text. This replacement requires the following thermodynamic assumption:

$$\frac{\alpha}{\rho} = -\frac{dS}{dP}\bigg|_T = \frac{dS}{dT}\bigg|_P \frac{dT}{dP}\bigg|_S \sim \frac{C_P}{T}\frac{dT}{dP}\bigg|^{Fluidity}, \tag{3}$$

where P, T and S are pressure, temperature and entropy, respectively; and α, ρ and C_P denote thermal expansivity, density and heat capacity, respectively.

The lherzolite melting parameterization of Katz et al. (2003) is a hydrous parameterization and so a weight fraction of water present within the source region (F_{H_2O}) must be estimated. F_{H_2O} in primitive mantle is assumed to be 280 ppm and is approximated from the concentration of Ce within the source region (F_{Ce}) by assuming that $F_{H_2O}/F_{Ce} = 200$ (Michael, 1995). F_{H_2O} in depleted mantle is taken to be 100 ppm (Salters & Stracke, 2004).

Text S2. Distribution Coefficients

To calculate the bulk distribution coefficient for a given element within the solid assemblage, $\bar{D}$, the partition coefficients for each mineral, D_{min}, must be parameterized. Our model includes two options for how D_{ol}, D_{opx}, D_{cpx} and D_{gar} are calculated. Partition

coefficients can either be assumed to be constant using the values listed in Table S1, or they can vary as a function of pressure (P), temperature (T) and mineral chemistry. D_{spl} is assumed to be constant as a function of P and X for all elements. In the mantle, partition coefficients necessarily vary as a function of P, T and mineral chemistry as sites within mineral lattices expand and contract. The partitioning of an element with a charge $v+$ and a radius r_i entering into site M of a crystalline lattice is governed by the lattice strain equation,

$$D_i = D_{0(M)}^{v+} \times \exp \left[\frac{-4\pi N_A E_M^{v+}}{RT} \left(\frac{1}{2} r_{0(M)}^{v+} \left(r_i - r_{0(M)}^{v+} \right)^2 + \frac{1}{3} \left(r_i - r_{0(M)}^{v+} \right)^3 \right) \right], \quad (4)$$

where N_A is Avogadro's number, R is the gas constant, E_M^{v+} is the Young's modulus of lattice site M, $r_{0(M)}^{v+}$ is the radius of the site and $D_{0(M)}^{v+}$ is the partition coefficient for an element with a charge $v+$ and a radius $r_{i(M)}^{v+}$ (Brice, 1975; Wood & Blundy, 1997). $v+$ and r_i for each element are listed in Table S1. Elemental radii are dependent upon the stoichiometry of the mineral site that the element is entering. For olivine, each element is in a six-fold coordination, r_i (VI), for pyroxene and garnet each element is in an eight-fold coordination, r_i (VIII). Note that any element where ionic radii in six- or eight-fold coordination is not recorded is assigned a constant partition coefficient for minerals that require those variables to calculate partition coefficients (McKenzie & O'Nions, 1995).

Olivine

For Olivine, $D_{0(M)}^{v+}$, E_M^{v+} and $r_{0(M)}^{v+}$ are calculated for 3+ valency cations, such as the REEs and Y, using the equations of Sun and Liang (2013),

$$D_{0(ol)}^{3+} = \exp \left(-0.45 - 0.11P + 1.54\chi_{\text{Mel}}^{\text{Al}} - 1.94\text{Mg\#} \right), \quad (5)$$

$$E_{ol}^{3+} = 426 \times 10^9, \quad (6)$$

$$r^{3+}_{0(ol)} = 0.72 \times 10^{-10}. \tag{7}$$

Where χ^{Al}_{min} is the modal proportion of Al in a mineral, which in this case is olivine (ol), and can be calculated by

$$\chi_i = i_{mol} \times C_i \times \frac{1}{O_{min}} \sum_i^I i_{mol}O_i, \tag{8}$$

$$\mathrm{Mg\#} = \frac{F^{\mathrm{Mg}}_{min}}{F^{\mathrm{Mg}}_{min} + F^{\mathrm{Fe}}_{min}}, \tag{9}$$

where χ_i, i_{mol}, C_i, O_i and O_{min} are the proportions of oxide i within the mineral, fraction by weight of oxide i within the mineral divided by its molecular weight, the number of cations in the oxide i, the number of oxygen atoms in the oxide i and the number of oxygen atoms in the mineral, respectively. O_{ol}, O_{opx}, O_{cpx} and O_{gnt} are 4, 6, 6 and 12, respectively. All other constants are listed in Table S2.

The partition coefficients between olivine and melt for elements with 1+, 2+, 4+ or 5+ valency are assigned using a compilation of constant values (McKenzie & O'Nions, 1995).

Orthopyroxene

The partition coefficients for +3 valency cations partitioning into orthopyroxene are calculated using the parameterization of Yao, Sun, and Liang (2012),

$$D^{3+}_{0(opx)} = \exp\left(-5.37 + \frac{38700}{RT} + 3.54\chi^T_{\mathrm{Al}} + 3.56\chi^{M2}_{\mathrm{Ca}}\right), \tag{10}$$

$$E^{3+}_{opx} = \left(-1.37 + 1.85r_0 - 0.53\chi^{M2}_{\mathrm{Ca}}\right) \times 10^{12}, \tag{11}$$

$$\text{where } r^{3+}_{0(opx)} = \left(0.69 + 0.23\chi^{M2}_{\mathrm{Mg}} + 0.43F^{M2}_{\mathrm{Ca}}\right) \times 10^{-10}. \tag{12}$$

Within pyroxenes, the amount of Ca, Mg and Al entering either the $M1$, $M2$ or tetrahedral site are calculated assuming all Ca, Na, K and Mn are assigned to the $M2$ site, all Ti and Cr are assigned to the $M1$ site, and that Fe and Mg are equally distributed across

$M1$ and $M2$ (Wood & Banno, 1973). Finally, any Al that cannot fit in the $M1$ site is assigned to the tetrahedral site so that,

$$\chi_{\text{Mg}}^{M2} = (1 - \chi_{\text{Ca}} - \chi_{\text{Na}} - \chi_{\text{K}} - \chi_{\text{Mn}}) \times \text{Mg}\#, \tag{13}$$

$$\chi_{\text{Ca}}^{M2} = \chi_{\text{Ca}}, \tag{14}$$

$$\chi_{\text{Al}}^{M1} = 1 - \chi_{\text{Ti}} - \chi_{\text{Cr}} - \left(\chi_{\text{Mg}} + \chi_{\text{Fe}} - \frac{\chi_{\text{Mg}}^{M2}}{\text{Mg}\#} \right), \tag{15}$$

$$\chi_{\text{Al}}^{T} = \chi_{\text{Al}} - \chi_{\text{Al}}^{M1}. \tag{16}$$

The constants within the lattice-strain model for $+2$ cations ($D_{0(opx)}^{2+}$, E_{opx}^{2+} and $r_{0(opx)}^{2+}$) are parameterized from the constants for $3+$ cations and relative to Mg (Hazen & Finger, 1979; Wood & Blundy, 2014),

$$E_{opx}^{2+} = \frac{2}{3} E_{opx}^{3+}, \tag{17}$$

$$r_{0(opx)}^{2+} = r_{0(opx)}^{3+} + 0.08 \times 10^{-10}, \tag{18}$$

$$r_{Mg} = 0.89 \times 10^{-10}, \tag{19}$$

$$D_i^{2+} = \exp\left[\frac{-4\pi N_A E_{opx}^{2+}}{RT} \left(\frac{r_0^{2+}}{2}(r_{\text{Mg}}^2 - r_i^2) + \frac{1}{3}(r_i^3 - r_{\text{Mg}}^3) \right) \right]. \tag{20}$$

For $1+$, $4+$ and $5+$ valency cations, partition coefficients between orthopyroxene and melt are assigned constant values from a compilation of experimental results (McKenzie & O'Nions, 1995).

Clinopyroxene

The partition coefficients between clinopyroxene and melt for $3+$ cations are set using the parameterization of Sun and Liang (2012),

$$D_{0(cpx)}^{3+} = \exp\left(-7.14 + \frac{7.19 \times 10^4}{RT} + 4.37\chi_{\text{Al}}^{M1} + 1.98\chi_{\text{Mg}}^{M2} - 0.91\chi_{\text{H}_2\text{O}} \right), \tag{21}$$

$$E_{cpx}^{3+} = \left(2270 r_{0(cpx)}^{3+} - 2000 \right) \times 10^9, \tag{22}$$

where $r_{0(cpx)}^{3+} = \left(1.066 - 0.104\chi_{Al}^{M1} - 0.212\chi_{Mg}^{M2}\right) \times 10^{-10}.$ (23)

The constants within the lattice-strain model for +1 cations ($D_{0(cpx)}^{1+}$, E_{cpx}^{1+} and $r_{0(cpx)}^{1+}$) are parameterized from the constants for 3+ cations and relative to D_{Na}^{1+} (Hazen & Finger, 1979; Blundy et al., 1995; Wood & Blundy, 2014),

$$D_0^{Na} = \exp\left(\frac{10367 + 2100P - 165P^2}{T} - 10.27 + 0.358P - 0.0184P^2\right),$$ (24)

$$r_{Na} = 1.18 \times 10^{-10},$$ (25)

$$r_0^{1+} = r_0^{3+} + 0.12 \times 10^{-10},$$ (26)

$$E_{cpx}^{1+} = \frac{1}{3}E_{cpx}^{3+},$$ (27)

$$D_i^{1+} = D_0^{Na}\exp\left[\frac{-4\pi N_A E_{cpx}^{1+}}{RT}\left(\frac{r_0^{1+}}{2}\left(r_{Na}^2 - r_i^2\right) + \frac{1}{3}\left(r_i^3 - r_{Na}^3\right)\right)\right].$$ (28)

Constants within the lattice-strain model for +2 cations are parameterized from the constants for 3+ cations and relative to D_{Ca}^{2+}

$$D_{0(cpx)}^{Ca} = 2,$$ (29)

$$r_{Ca} = 1.12 \times 10^{-10},$$ (30)

$$E_{cpx}^{2+} = \frac{2}{3}E_{cpx}^{3+},$$ (31)

$$r_{0(cpx)}^{2+} = r_{0(cpx)}^{3+} + 0.06 \times 10^{-10},$$ (32)

$$D_i^{2+} = D_0^{Ca}\exp\left[\frac{-4\pi N_A E_{cpx}^{2+}}{RT}\left(\frac{r_0^{1+}}{2}\left(r_{Ca}^2 - r_i^2\right) + \frac{1}{3}\left(r_i^3 - r_{Ca}^3\right)\right)\right]$$ (33)

(Hazen & Finger, 1979; Blundy & Wood, 2003; Hill et al., 2011; Wood & Blundy, 2014). Constants within the lattice-strain model for +4 cations are parameterized from the constants for 3+ cations and relative to D_{Th}^{4+} (Hazen & Finger, 1979; Landwehr et al., 2001; Wood & Blundy, 2014),

$$D_{0(cpx)}^{Th} = \exp\left(\frac{214790 - 175.7T + 16420P - 1500P^2}{RT}\right)\frac{\chi_{Mg}^{Mel}}{\chi_{Mg}^{M1}Y_{Mg}^{M1}Y_{Th}^{M2}},$$ (34)

$$E_{cpx}^{4+} = \frac{4}{3} E_{cpx}^{3+}, \tag{35}$$

$$r_{0(cpx)}^{4+} = r_{0(cpx)}^{3+}, \tag{36}$$

$$r_{\text{Th}} = 1.041 \times 10^{-10}, \tag{37}$$

$$D_i^{4+} = D_{0(cpx)}^{\text{Th}} \exp \left[\frac{-4\pi N_A E_{cpx}^{4+}}{RT} \left(\frac{r_0^{4+}}{2} \left(r_{\text{Th}}^2 - r_i^2 \right) + \frac{1}{3} \left(r_i^3 - r_{\text{Th}}^3 \right) \right) \right], \tag{38}$$

$$\text{where } Y_{\text{Mg}}^{M1} = \exp \left[\frac{902 \left(1 - \chi_{\text{Mg}}^{M1} \right)^2}{T} \right], \tag{39}$$

$$\text{and } Y_{\text{Th}}^{M2} = \exp \left[\frac{4\pi N_A E_{cpx}^{4+}}{RT} \left(\frac{r_0^{4+}}{2} \left(r_{\text{Th}} - r_0^{4+} \right)^2 + \frac{1}{3} \left(r_{\text{Th}} - r_0^{4+} \right)^3 \right) \right]. \tag{40}$$

A constant partition coefficient between melt and clinopyroxene is used for elements with 5+ valency (McKenzie & O'Nions, 1995).

Garnet

The partition coefficients between garnet and melt for elements with 3+ valency are parameterized using the equations of Sun and Liang (2013),

$$D_{0(gar)}^{3+} = \exp \left(-2.05 + \frac{91700 - 3471.3P + 91.35P^2}{RT} - 1.02\chi_{\text{Ca}} \right), \tag{41}$$

$$E_{gar}^{3+} = \left(-1620 + 2290 r_{0(gar)}^{3+} \right) \times 10^9, \tag{42}$$

$$\text{where } r_{0(gar)}^{3+} = (0.78 + 0.155\chi_{\text{Ca}}) \times 10^{-10}. \tag{43}$$

The constants within the lattice-strain model for elements with +2 valency are parameterized from the constants for elements with 3+ valency and relative to D_{Mg}^{2+} (Hazen & Finger, 1979; Wood & Blundy, 2014),

$$E_{gar}^{2+} = \frac{2}{3} E_{gar}^{3+}, \tag{44}$$

$$r_{0(gar)}^{2+} = r_{0(gar)}^{3+} + 0.053 \times 10^{-10}, \tag{45}$$

$$r_{\text{Mg}} = 0.89 \times 10^{-10}, \tag{46}$$

$$D_{\mathrm{Mg}} = \frac{\exp\left(\dfrac{258210 - 141.5T + 5418P}{3RT}\right)}{\exp\left(\dfrac{19000\chi_{\mathrm{Ca}}^2}{RT}\right)}, \tag{47}$$

$$D_i^{2+} = D_{\mathrm{Mg}}\exp\left[\frac{-4\pi N_A E_{gar}^{2+}}{RT}\left(\frac{r_0}{2}\left(r_{\mathrm{Mg}}^2 - r_i^2\right) + \frac{1}{3}\left(r_i^3 - r_{\mathrm{Mg}}^3\right)\right)\right]. \tag{48}$$

The constants within the lattice-strain model to calculate partition coefficients between garnet and melt for elements with +4 valency are parameterized using the values of Mallmann and O'Neill (2007),

$$D_{0(gar)}^{4+} = 4.38, \tag{49}$$

$$E_{gar}^{4+} = 2753 \times 10^9, \tag{50}$$

$$r_{0(M)}^{v+} = 0.6626 \times 10^{-10}. \tag{51}$$

Partition coefficients for elements with 1+ or 5+ valency are parameterized as fixed values (McKenzie & O'Nions, 1995).

Spinel

Partition coefficients between spinel and melt for all elements are assumed to be constant values (McKenzie & O'Nions, 1995).

Text S3. Peridotite Model Description

Mineral Compositions

Mineral compositions are required to calculate bulk partition coefficients (Sun & Liang, 2012; Yao et al., 2012; Sun & Liang, 2013). The same experimental database outlined in Section 2 of the main text is used to parameterize mineral compositions as a function of pressure and/or melt fraction (Baker & Stolper, 1994; Falloon et al., 1999; Walter, 1998).

Olivine

Figure S3 shows χ_{Al} and Mg# in olivine as a function of melt fraction. The presence of garnet as a stable phase significantly alters the compositions of other minerals so that parameterizations for spinel- and garnet-bearing peridotites must be calibrated individually. χ_{Al} does not vary with pressure or melt fraction and is fixed as 0.00156 and 0.00564 in spinel- and garnet-bearing peridotites, respectively (Figures S3a,b). Mg# increases as melt fraction (X) increases by

$$\text{Mg\#} = 0.059X + 0.904 \text{ and Mg\#} = 0.070X + 0.897 \tag{52}$$

for spinel- and garnet- peridotite, respectively (Figures S3c,d).

Orthopyroxene

Orthopyroxene compositions vary differently with melt fraction depending on whether clinopyroxene is a stable phase. When clinopyroxene is stable, χ_{Mg}^{M2} decreases and χ_{Ca}^{M2} increases as melt fraction increases. These trends reverse when clinopyroxene is exhausted (Figure S4). There is no significant difference in orthopyroxene composition as a function of pressure or aluminous phase. Therefore we fit χ_{Mg}^{M2}, χ_{Al}^{T} and χ_{Ca}^{M2} in orthopyroxene using a second order polynomial on all available data,

$$\chi_{\text{Mg}}^{M2} = 0.692X^2 - 0.176X + 0.834, \tag{53}$$

$$\chi_{\text{Al}}^{T} = -0.675X^2 + 0.041X + 0.146, \tag{54}$$

$$\chi_{\text{Ca}}^{M2} = -0.756X^2 + 0.273X + 0.063. \tag{55}$$

Clinopyroxene

203   χ_{Mg}^{M2}, χ_{Al}^{T}, and χ_{Al}^{M1} in clinopyroxene vary linearly as a function of melt fraction but

204 depend significantly on whether garnet is a stable phase (Figure S5). If spinel is stable,

205    $$\chi_{\text{Mg}}^{M2} = 0.583X + 0.223,\ \chi_{\text{Al}}^{T} = -0.177X + 0.154,\ \text{and}\ \chi_{\text{Al}}^{M1} = -0.438X + 0.137, \quad (56)$$

206 and if garnet is stable,

207    $$\chi_{\text{Mg}}^{M2} = 0.422X + 0.547,\ \chi_{\text{Al}}^{T} = -0.013X + 0.061,\ \text{and}\ \chi_{\text{Al}}^{M1} = -0.114X + 0.099. \quad (57)$$

208 To calculate partition coefficients between clinopyroxene and melt for elements with +4

209 valency requires a parameterization for χ_{Mg}^{M1} and χ_{Mg}^{Mel}. Both χ_{Mg}^{M1} and χ_{Mg}^{Mel} vary linearly

210 as a function of X and strongly depend on whether spinel- or garnet-bearing peridotite is

211 melting (Figure S5). If spinel is stable, χ_{Mg}^{M1} and χ_{Mg}^{Mel} can be parameterized as

212    $$\chi_{\text{Mg}}^{M1} = 0.425X + 0.741 \text{ and } \chi_{\text{Mg}}^{Mel} = 0.140X + 0.722, \quad (58)$$

213 whereas if garnet is stable,

214    $$\chi_{\text{Mg}}^{M1} = 0.191X + 0.793 \text{ and } \chi_{\text{Mg}}^{Mel} = 0.207X + 0.701. \quad (59)$$

Garnet

215   Finally, χ_{Ca} in garnet decreases as a function of melt fraction,

216    $$\chi_{\text{Ca}} = -0.247X + 0.355. \quad (60)$$

Text S4. Calculating x_f Using Extraction Efficiency

217   Extraction efficiency is defined as the ratio of the volume of melt erupted over the

218 total volume of melt produced (Keller et al., 2017). To calculate the expected extraction

August 26, 2021, 3:45pm

efficiency within our simulations based on the extraction efficiency results of Keller et al.

(2017) we must correct for three factors. First, their simulations of varying T_p have a

constant R_s of 3 cm yr^{-1}, whereas our models have an R_s of 2.1 cm yr^{-1}. Second, their

simulations of varying R_s have a constant T_p of 1350 °C, while ours have a T_p of 1325 °C.

Third, to provide a better fit to crustal thickness observations, Keller et al. (2017) reduce

their MORB proportion from 25% to 19% and so the results published in Figure 4 of

their paper cannot be used directly. Therefore, we apply the following approach. First,

we calculate regressions through their extraction efficiency results as a function of R_s, T_p

and MORB proportion for a bulk mantle source (open squares in Figures 4f, 4h and 4i of

Keller et al., 2017). Then, for each parameter, we compute the difference in extraction

efficiency between their reference value and ours (e.g., the difference between extraction

efficiency at $R_s = 3$ cm yr^{-1} and 2.1 cm yr^{-1}). Finally, using linear combinations of the

obtained differences (e.g. differences in MORB content and half-spreading rate for data at

variable potential temperature), we adjust Keller et al. (2017) extraction efficiency results

and calculate new regressions applicable to our simulations.

In this context, we define x_f as the lateral distance from the ridge axis encompassing

a volume of melt equal to the extraction efficiency times the total amount of melt pro-

duced within the whole melting region. In doing so, we assume full melt extraction at

distances $< x_f$ and exclude any contribution from melts generated farther away. For each

of our simulations, we use the previously obtained regressions to compute the extraction

efficiency and deduce x_f accordingly.

A parameterized model for REE distribution between low-Ca pyroxene and basaltic melts with applications to REE partitioning in low-Ca pyroxene along a mantle adiabat and during pyroxenite-derived melt and peridotite interaction. *Contributions to Mineralogy and Petrology*, *164*(2), 261–280.
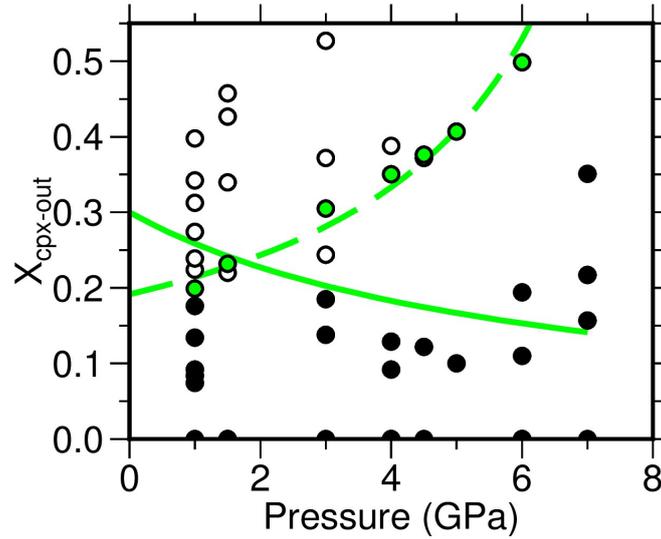

Figure S1.   Comparison between anhydrous melting model parameterisation predictions of the melt fraction at which clinopyroxene is exhausted ($X_{cpx-out}$) as a function of pressure. Closed/open circles = peridotite melting experiments where clinopyroxene is present/absent in the residue (Baker & Stolper, 1994; Walter, 1998; Falloon et al., 1999). Green circles = $X_{cpx-out}(P)$ constrained by fitting to experimental data, note that experiments conducted at 3 and 5 GPa were not used to predict modal mineralogy (see Section 3.2 of main text). Solid/dashed line = original/updated melting parameterization (Katz et al., 2003).
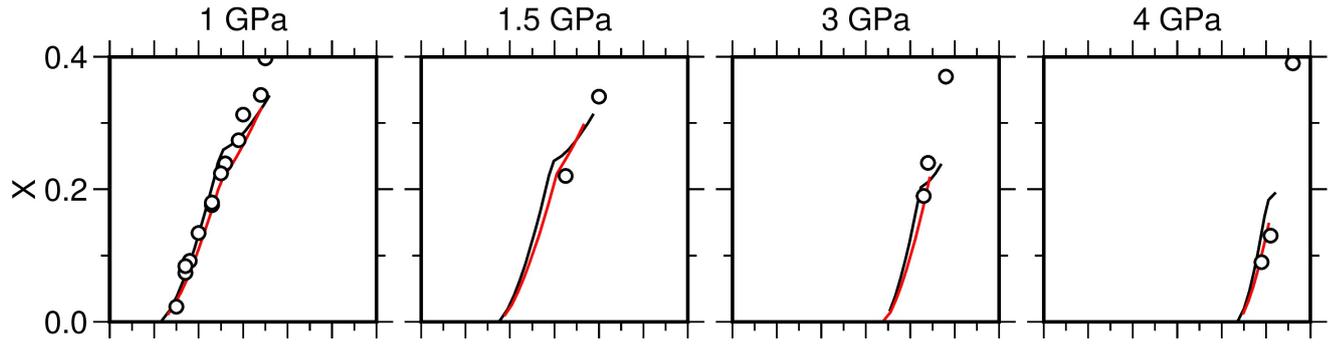

Figure S2. Comparison between experimental data and anhydrous melting model parameterisations at different pressures. Open circles = experimental results used to constrain our geochemical melting model (Baker & Stolper, 1994; Walter, 1998; Falloon et al., 1999). Black/red line = original/updated melting parameterization (Katz et al., 2003). Melting models are calculated from to $T_p = 1100$–$1650\ ^\circ$C

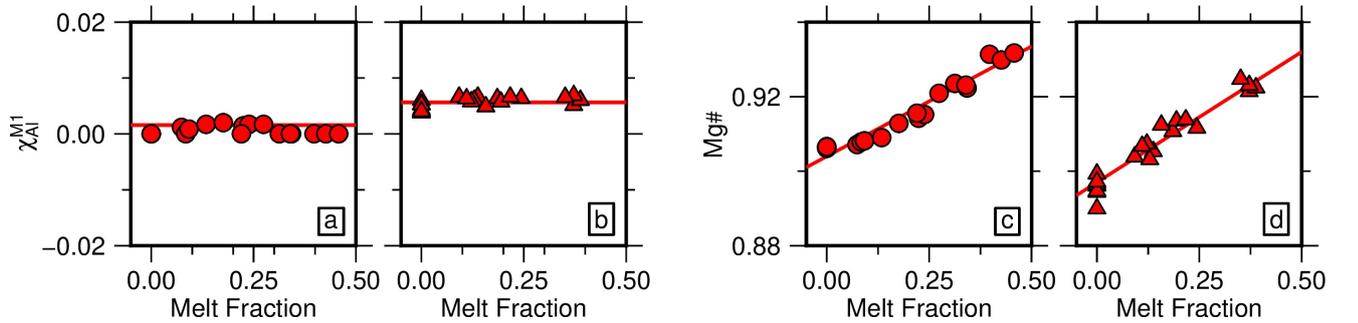

Figure S3. Olivine composition as a function of melt fraction, red circles/triangles = spinel/garnet peridotite melting experiments. Red lines = best-fit parameterisation described by Equation 52. a) χ_{Al}^{M1} as function of X for spinel peridotite. b) Same for garnet peridotite. c) Mg# as function of X for spinel peridotite. d) Same for garnet peridotite.
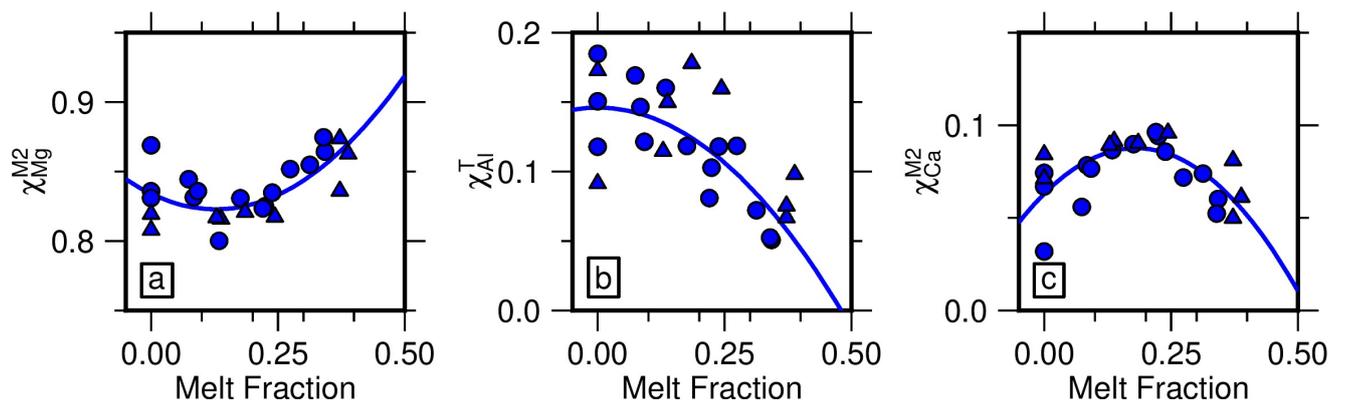

Figure S4.   Orthopyroxene composition as a function of melt fraction, blue circles/triangles = spinel/garnet peridotite melting experiments. Blue lines = best-fit regression lines. a) χ_{Mg}^{M2} as a function of X, regression described by Equation 53. b) χ_{Al}^{T} as a function of X, regression described by Equation 54. c) χ_{Ca}^{M2} as a function of X, regression described by Equation 55.
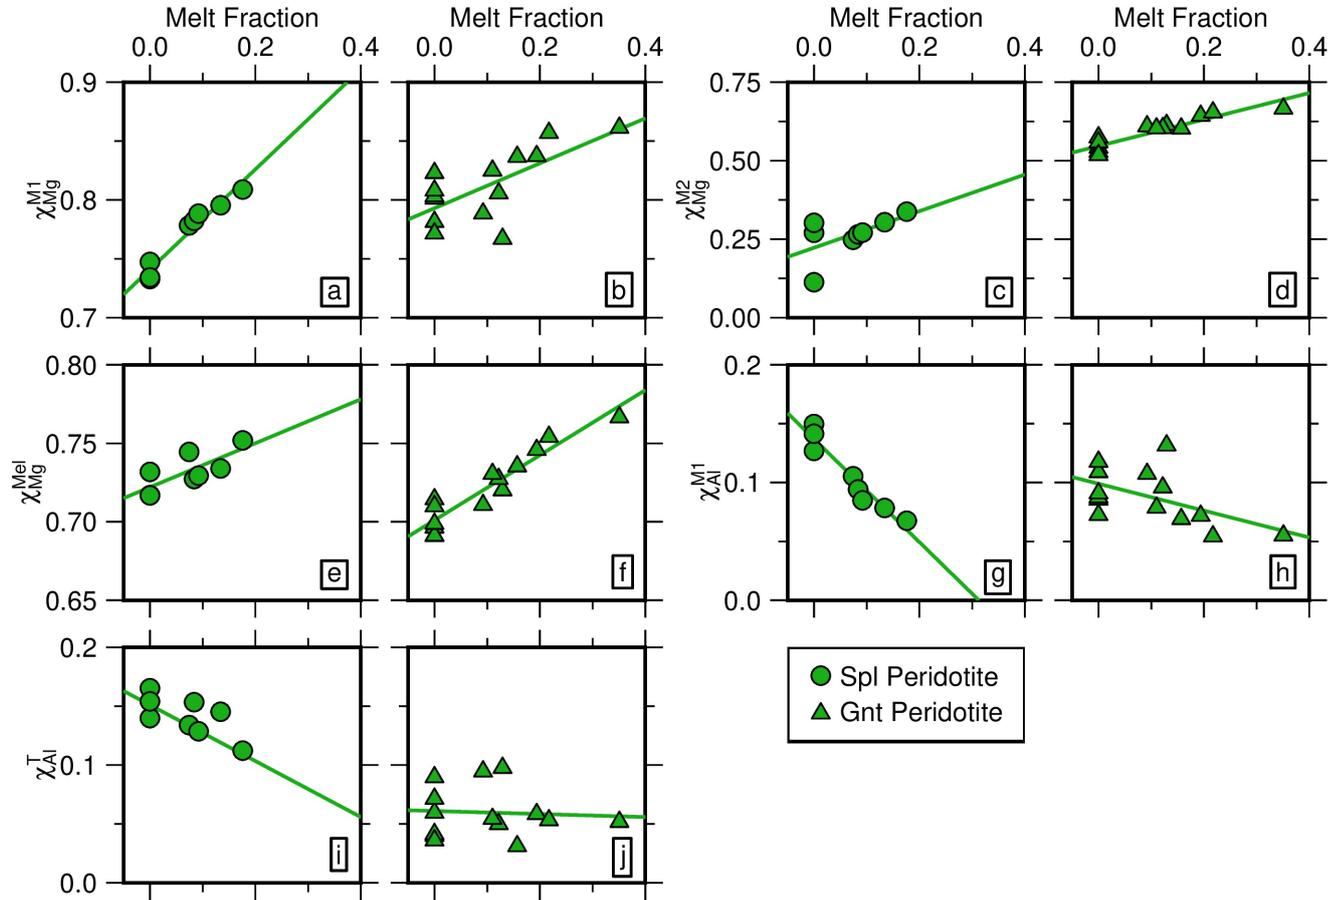

Figure S5.   Clinopyroxene composition as a function of melt fraction, green circles/triangles = spinel/garnet peridotite melting experiments. Green lines = best-fit linear regressions for each set of compositions. a/b) $\chi_{\mathrm{Mg}}^{\mathrm{M1}}$ as function of X, regression described in Equation 56/57. c/d) same for $\chi_{\mathrm{Mg}}^{\mathrm{M2}}$. e/f) same for $\chi_{\mathrm{Mg}}^{\mathrm{Mel}}$. g/h) same for $\chi_{\mathrm{Al}}^{\mathrm{M1}}$. i/j) same for $\chi_{\mathrm{Al}}^{\mathrm{T}}$.
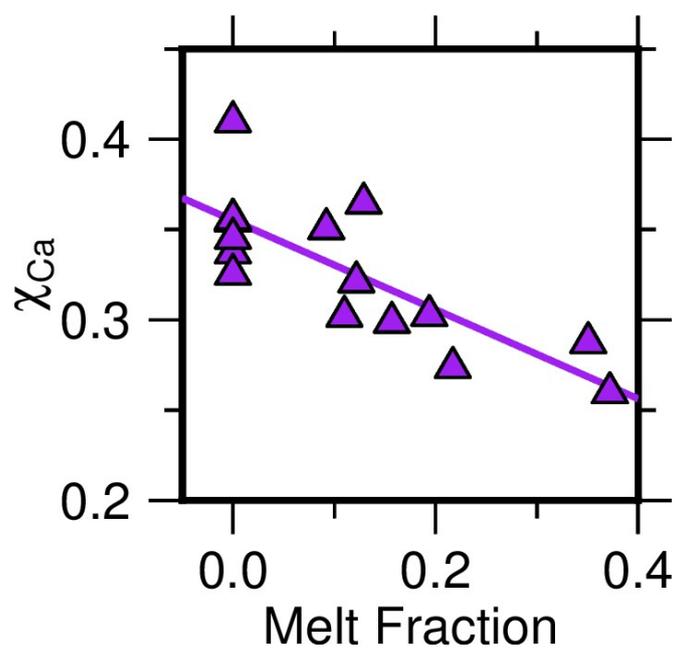

Figure S6. χ_{Ca} in garnet as a function of melt fraction, purple triangles = garnet peridotite melting experiments. Purple line = best-fit regression described by Equation 60.
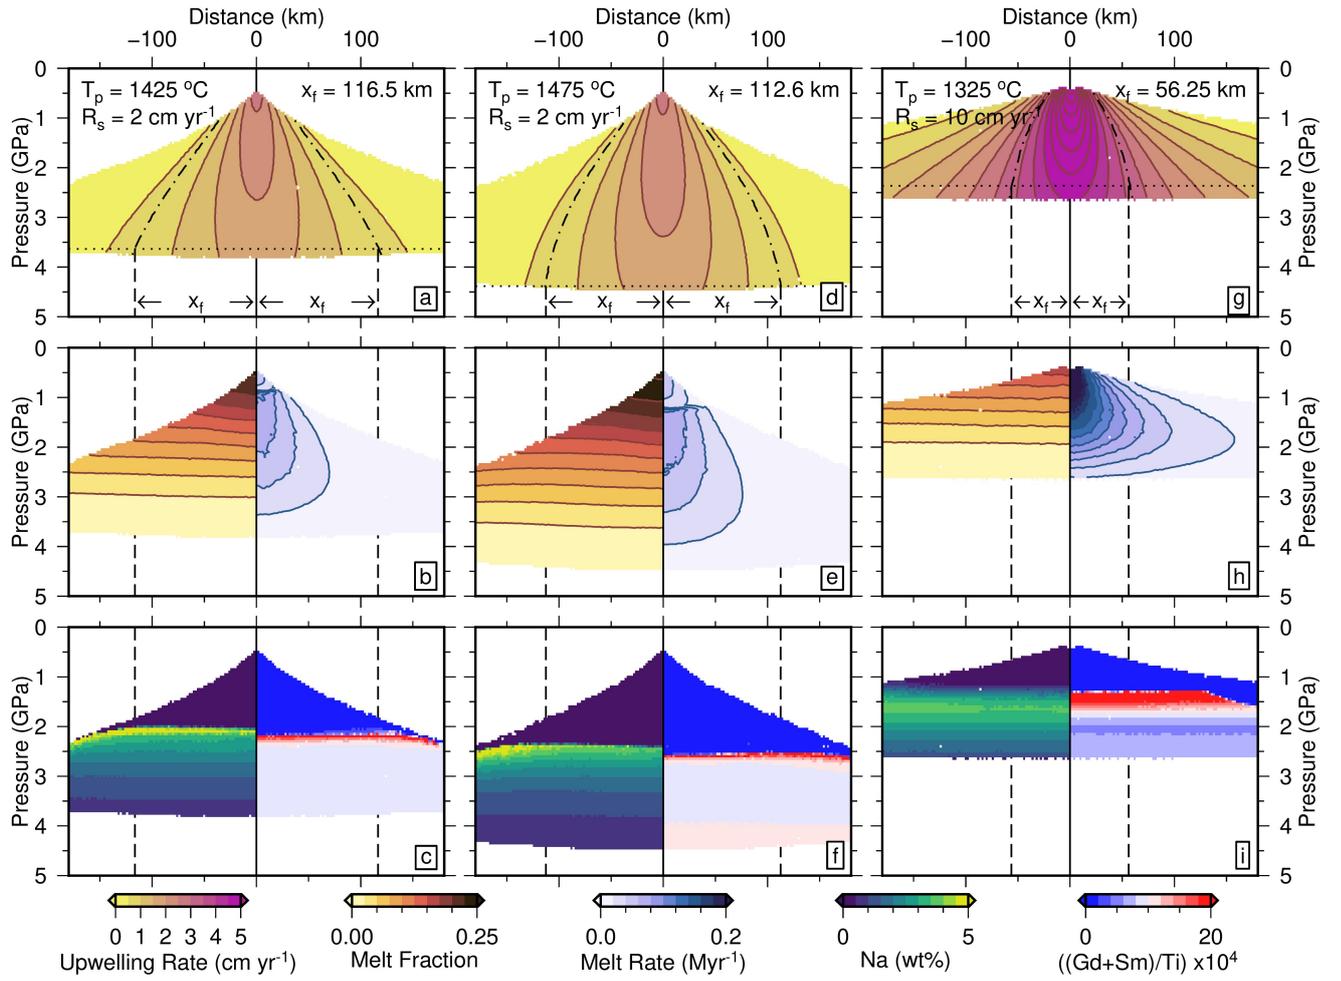

Figure S7. Melt region geometry at mid-oceanic ridges as a function of T_p and R_s. a) Ridge-centred model coloured by upwelling rate. Coloured region indicates where $X > 0$. Model run with T_p and R_s as indicated top-left; corresponding x_f for each model shown top right. b) Same as panel a but with left- and right-hand sides coloured by melt fraction and melting rate, respectively. c) Same as panel a but with left- and right-hand sides coloured by Na wt% and $((Gd+Sm)/Ti)x10^4$ within the instantaneous melt phase, respectively. d–f) Same as panels a–c but with different T_p and R_s as indicated in top left corner of panel d. g-i) Same as panels d-f.
