**Abstract**

We report a portable and robust home-built atom gravimeter (USTC-AG11) continuously working in a seismic station over 5 months. Based on the principle of matter-wave interference, the atom gravimeter is very sensitive to the local gravity and can reach the precision of micro-Gal ( $1 \times 10^{-8} \text{m/s}^2$ ) level. With the technique of vibrational compensation, the sensitivity of the atom gravimeter reaches  $38 \mu\text{Gal}/\sqrt{\text{Hz}}$ , which is almost immune to the ground vibration noise. The design of the atom gravimeter in the electronics and laser optics, especially the laser frequency and phase auto-relock technology, guarantees the long term continuous running. The long-term precision of the atom gravimeters is better than  $2 \mu\text{Gal}$ , which is comparable to the best classical gravimeter FG-5(X). Our work provides a novel application for the high precision atomic gravimeter based on modern quantum sensing technology in the field of geophysics and geodesy survey.

**1 Introduction**

Since the pioneering work started by Mark Kasevich and Steve Chu in 1991 (Kasevich & Chu, 1991), atom interferometry has accessed to long-term development and grown into a successful tool for precision measurements. Nowadays, atom interferometer has been extensively used in the fields such as measurements of gravity acceleration (Peters et al., 1999, 2001; Hu et al., 2013; Freier et al., 2016; Farah et al., 2014; M enoret et al., 2018), gradiometry (Snadden et al., 1998; Sorrentino et al., 2014; Duan et al., 2014), rotation (Gustavson et al., 1997; Canuel et al., 2006; Dutta et al., 2016; Yao et al., 2016) and tests of fundamental physical laws (Rosi et al., 2014; Parker et al., 2018; Chaibi et al., 2016; M uller et al., 2008; Schlippert et al., 2014; Tarallo et al., 2014; Duan et al., 2016; Overstreet et al., 2018). Atom gravimeter (AG), one of the most significant embranchment of atom interferometers, has attracted much attention as a result of its existing performance and potential (Gillot et al., 2014), since the precise gravity measurement is valuable in broad areas such as geophysics, geodesy and aided inertial navigation based on gravity reference map. At present, the research interests of atom gravimeter are most focused on applications. Portable atom gravimeters are developed towards field applications, which has become a research priority (Fang et al., 2016; Bongs et al., 2019).

Through the developments over two decades, the sensitivity and accuracy of atom gravimeters have reached the level of several  $\mu\text{Gal}$  ( $1 \mu\text{Gal} = 10^{-8} \text{m/s}^2$ ), which is comparable with a high precision commercial classical gravimeter such as FG-5(X) and A10. In ICAG-2017, six atom gravimeters took part in the comparison, and four of their results are recorded into the official report (WU et al., 2020). Recently, a commercial atom gravimeter AQG-B from  $\mu\text{Quants}$  company is successfully installed on Etna Volcano, and used to observe the variation of the gravity caused by the underground dynamics (Antoni-Micollier et al., 2022). Not only for static gravity measurements, the atom gravimeters are also applied in different moving platforms. M uller’s group from University of California performed a field gravity survey along a route of about 7.6 kilometers in Berkeley Hills using a mobile atom gravimeter (Wu et al., 2019); Huazhong University of Science and Technology (HUST) reported a car-based portable atom gravimeter that revealed the density distribution of a hill located in HUST campus (Zhang et al., 2021); Zhejiang University of technology (ZJUT) also performed a gravity survey with their atom gravimeter around the Xianlin reservoir in Hangzhou City (Wang et al., 2022). The French aerospace laboratory ONERA developed a marine atom gravimeter and implemented it in real sea condition with a measurement accuracy better than  $1 \text{mGal}$  (Bidel et al., 2018), besides, they also loaded it on an airplane to perform the gravity survey in Iceland (Bidel et al., 2020); ZJUT and Innovation academy for precision measurement science and technology, Chinese Academy of Science, also reported their ship-borne atom gravimeter (Bing et al., 2021; Che et al., 2022).

**Figure 1.** (a) The Schematic of sensor head, it presents the basic structure of sensor head. (b) The location of USTC-AG11 on satellite map, insert picture is the real field gravity measurement of USTC-AG11.

70 Compared to the classical gravimeter, the atom gravimeter use the laser cooled atoms  
 71 as the test mass. It do not have any mechanical movement, therefore mechanical wear  
 72 has avoided completely, this unique attribute brings AG excellent long term uninterrupted  
 73 output performance. In this paper, aiming towards the precision gravity measurements  
 74 for seismic station, we report a portable and compact atom gravimeter named USTC-  
 75 AG11 based on matter wave interferometry. We transport the AG over 2200 Km from  
 76 Shanghai to Zhaotong, Yunnan province, and deploy the AG in a local seismic station  
 77 and carried out a long term  $g$  survey over five months. The sensitivity, the long-term sta-  
 78 bility and the overall accuracy of USTC-AG11 respectively are  $38 \mu\text{Gal}/\sqrt{\text{Hz}}$ , better than  
 79  $1 \mu\text{Gal}$  and about  $2 \mu\text{Gal}$ , which is same level as the best classical gravimeter FG-5(X).  
 80 Our result implies that the atom gravimeter is an ideal instrument for long-term pre-  
 81 cise measurements of gravity acceleration  $g$  in the near future.

82 **2 Setup of the atom gravimeter**

83 The assembly of USTC-AG11 atom gravimeter consists of three parts, it is con-  
 84 tains a miniaturized sensor head, a compact laser package and a electrical control sys-  
 85 tem.

86 The miniaturized sensor head has a dimension of only  $30\text{cm} \times 30\text{cm} \times 65\text{cm}$ . There  
 87 are three regions in the sensor head: the atoms preparation region, the matters wave in-  
 88 terferometry region and the quantum state detection region, as shown in Fig.1. The vac-  
 89 uum chamber was made by non-magnetic metal titanium with a  $10^{-9}$ mbar level vacuum  
 90 degree.

91 A compact laser package has been designed for providing all laser beams to ma-  
 92 nipulate the quantum states of  $^{87}\text{Rb}$  atom. All laser beams are supplied via two diode  
 93 lasers and a tapered amplifiers (TA). One of the Diode Lasers is locked with a magnetic-  
 94 enhanced modulated-transfer spectral(ME-MTS)(Long et al., 2018), the other one is phase-  
 95 locked using a optical-phase lock loop and amplified by TA. A laser frequency auto-locked  
 96 scheme is designed to ensure that the AG can work without long time interval. The lasers  
 97 are all integrated in a  $46\text{cm} \times 42\text{cm} \times 15\text{cm}$  solid module to achieve mechanical stabil-  
 98 ity and compactness.

99 The electrical control system chassis for the laser controller, time or clock controller,  
 100 as well as data acquisition modules are all integrated in three standard 3U 19 inches elec-  
 101 tronic boxes and mounted together with the optics module in a 56cm × 68cm × 72cm  
 102 rack. The total power consumption is less than 250 Watt.

### 103 3 Performance of AG in a field seismic station

104 The analysis of long-term gravity anomaly provides an efficient method to help iden-  
 105 tify a incoming earthquake. Since AG can perform a continuous drift-free absolute grav-  
 106 ity measurement, it may pave a new way to reveal a continuous record of gravity anomaly.  
 107 To verify this, we move USTC-AG11 to the Tianhetai seismic station(TSS) located at  
 108 Ludian, Zhaotong, Yunnan Province. Fig.1 shows the location of our AG on satellite map.  
 109 The inset of Fig.1 shows the real field gravity measurement.

110 During the measurement of gravitational acceleration  $g$ , we utilize a high-sensitive  
 111 seismometer Gralp-3ESPC to record the vibration data and calculate the phase shift  
 112  $\phi_{\text{vib}}$  caused by fluctuation of Raman reflector. This phase shift is given by

$$\begin{aligned}\phi_{\text{vib}} &= k_{\text{eff}}(z_g(0) - 2z_g(T) + z_g(2T)) \\ &= k_{\text{eff}} \int_0^{2T} g_s(t)v_g(t)dt \\ &= k_{\text{eff}}K_s \int_0^{2T} g_s(t)U_s(t)dt\end{aligned}$$

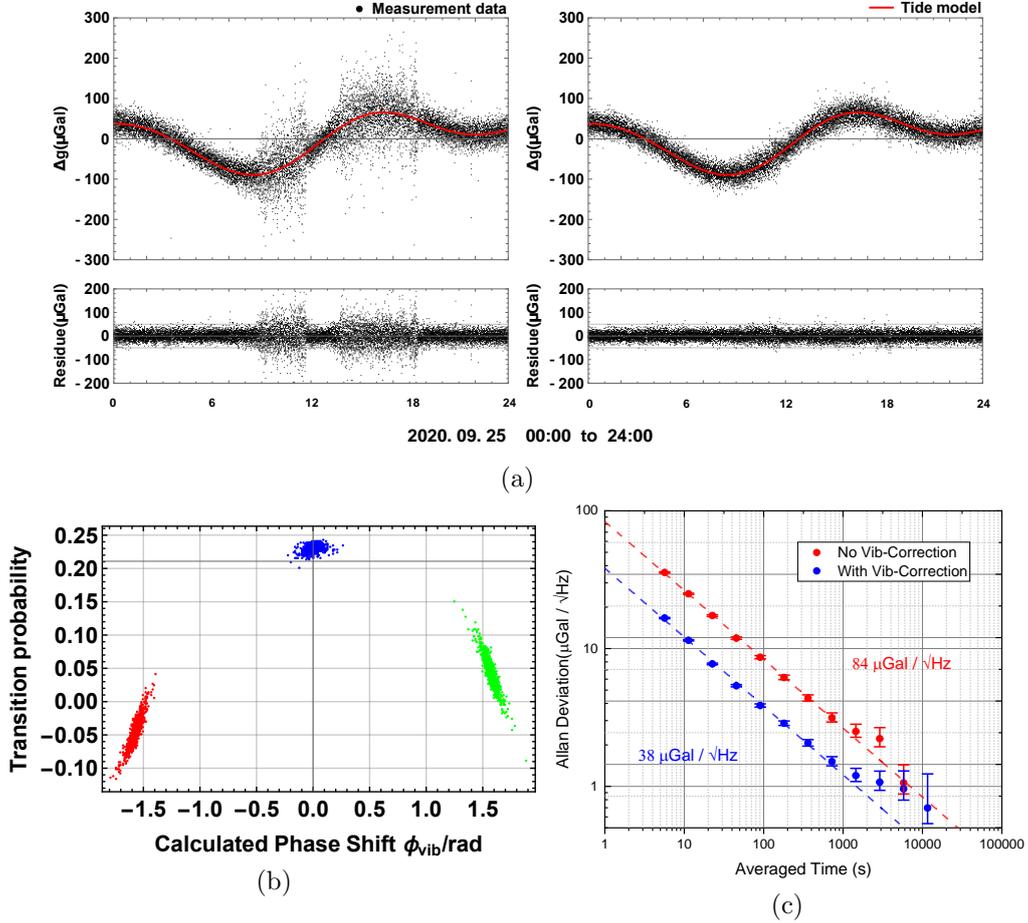

113 where  $T$ ,  $k_{\text{eff}}$ ,  $z_g$  ( $v_g$ ),  $U_s(t)$  and  $K_s(t) = 2000\text{v/m/s}$  are respectively interaction  
 114 time between each raman pulse, effective raman wave vector, the position (velocity) of  
 115 Raman reflector of sensor head, the output voltage of the seismometer and the conver-  
 116 sion factor of this seismometer, as well as the sensitive function  $g_s(t)$  can expressed as

$$g_s(t) = \begin{cases} -1 & 0 < t < T, \\ 1 & T < t < 2T. \end{cases} \quad (1)$$

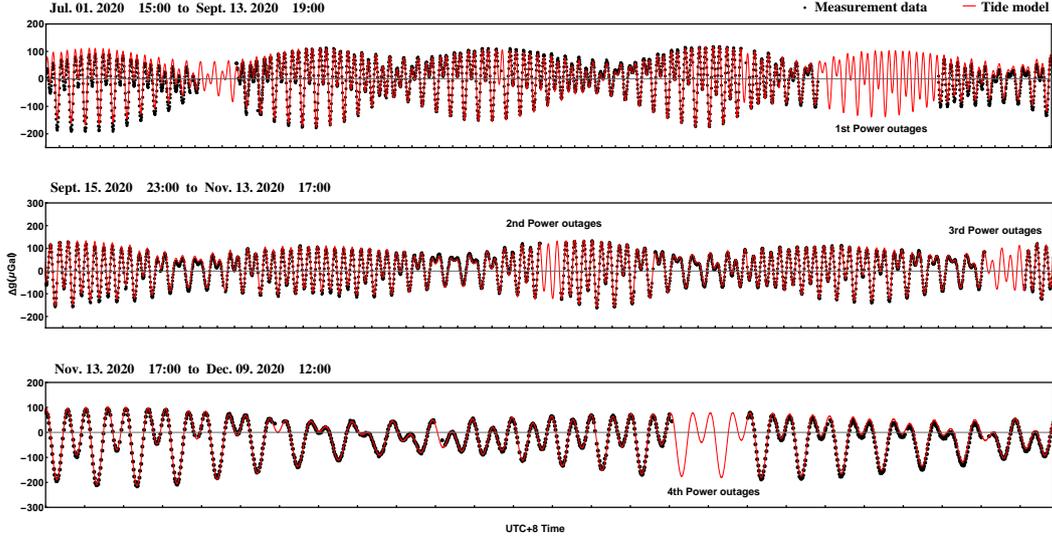

117 To demonstrate the validity of this vibrational post-correction method, we picked  
 118 out a solid tide match from a whole day Sept. 25th 2020 to calculate the sensitivity be-  
 119 fore and after vibration noise post-correction. As shown in Fig.2, the black dot is the  
 120 measured  $g$  data by USTC-AG11, the red line is the Earth solid tide model, which is cal-  
 121 culated by *Tsoft* software, a general tool to calculate the Earth tide model. Fig.2 (a)  
 122 shows the solid tide match and the residue obtained by minus tide model from measured  
 123  $g$  value. During this day, we can clearly see the difference before and after vibration cor-  
 124 rection, especially at the working time such as nearly 9 to 12 o'clock and 14 to 19 o'clock  
 125 in daytime. The straight distance between the TSS and the locally constructed roads  
 126 is several kilometers, which may be the major source of the measurement noise.

127 To further explain the vibration correction method of our AG, we calculate the cor-  
 128 relation factor between the phase shift caused by vibration noise and the population prob-  
 129 ability of atoms in  $|F = 1\rangle$ , as shown in Fig.2 (b). we find a correlation factor as high  
 130 as 0.92, that means that most of the vibration noise can be effectively corrected.

131 To evaluate the noise level of our AG, the sensitivity of our AG is calculated by  
 132 using standard Allan deviation, which is shown in Fig.2 (c). With vibration correction,  
 133 the sensitivity has been improved significantly from  $84 \mu\text{Gal}/\sqrt{\text{Hz}}$  to  $38 \mu\text{Gal}/\sqrt{\text{Hz}}$ , which  
 134 improves the sensitivity by approximately 55%. At the same time, the stability can reach  
 135  $1 \mu\text{Gal}@1200$  seconds with vibration correction. Thus, this method of suppressing vi-

**Figure 2.** (a) The experimental data of the gravitational constant  $g$  (the black dot) measured by USTC-AG11 from 0 o'clock to 24 o'clock, on Sept. 25 2020. The red curve is calculated by *Tsoft* software based on the earth solid tide model. The original data (left) measured directly by USTC-AG11 is processed by a efficient vibration noise correction (right). (b) The correlation factor between the phase shift caused by vibration noise and the population probability of atoms in  $|F = 1\rangle$ , 0.92 correlation factor. (c) The standard Allan deviation with vibration correction. The sensitivity has been improved significantly from 84  $\mu\text{Gal}/\sqrt{\text{Hz}}$  to 38  $\mu\text{Gal}/\sqrt{\text{Hz}}$ , which improves the sensitivity by approximately 55%.

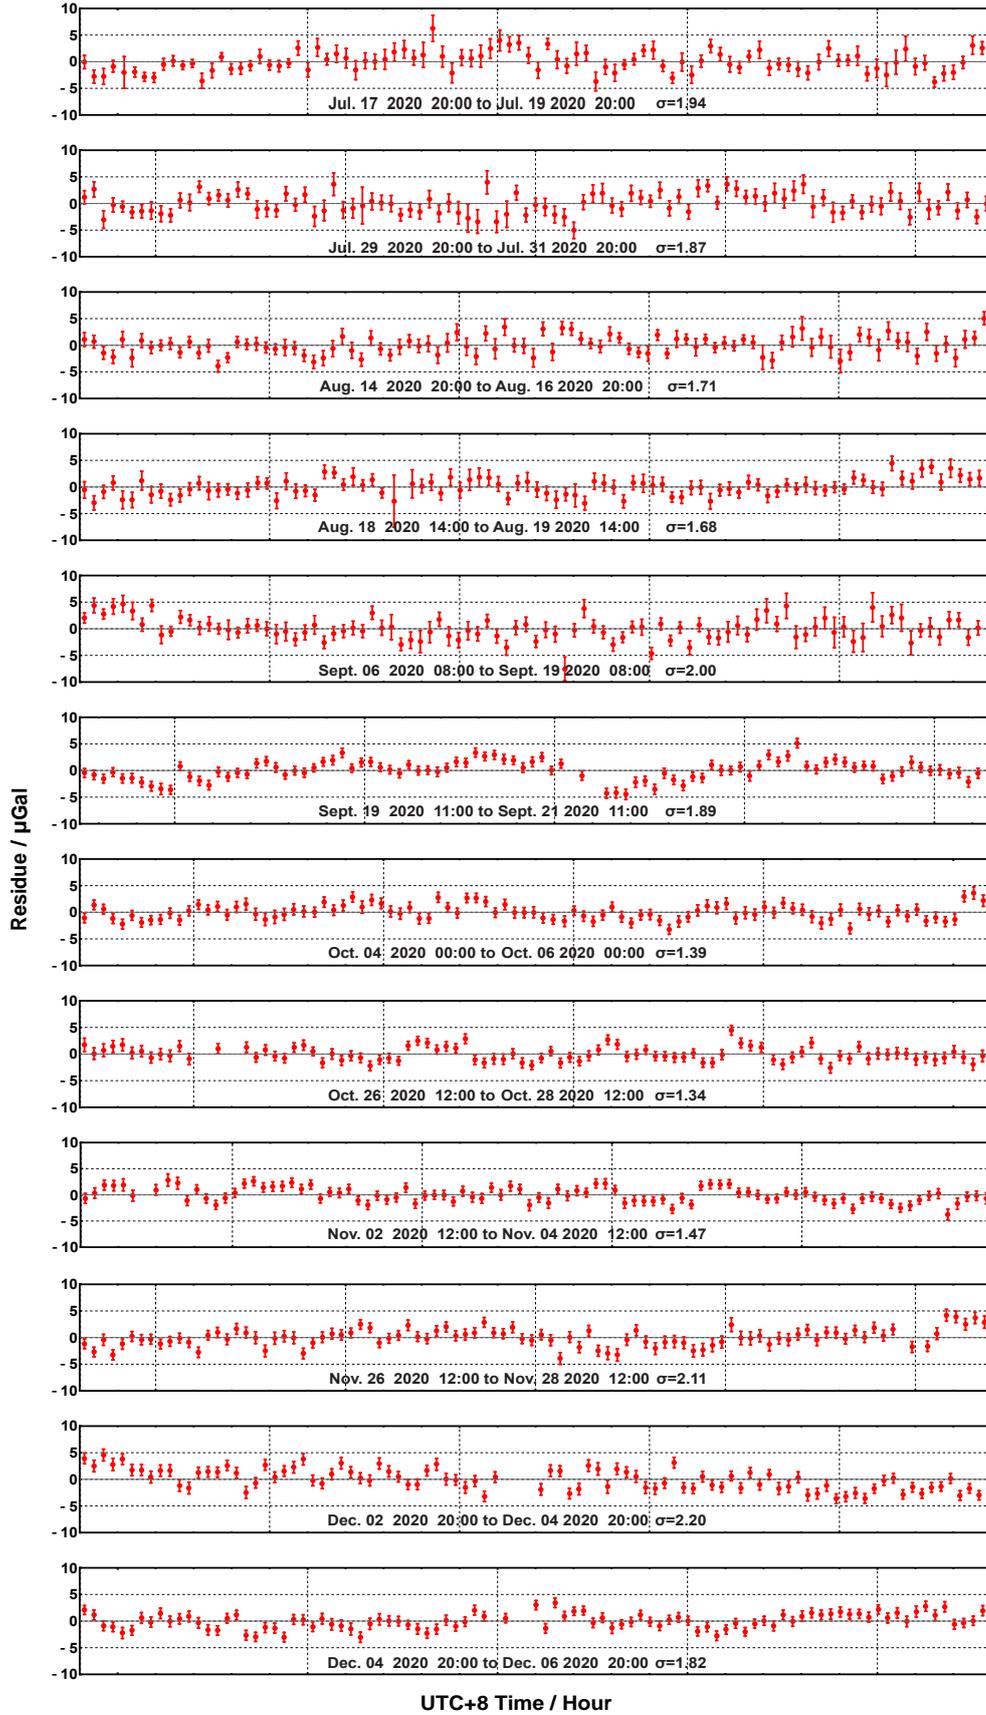

**Figure 3.** Continuous stable unattended gravity measurement carried out by USTC-AG11 lasting for more than five months in TSS. The black points are the gravity values measured by USTC-AG11, each black point is averaged by half hour; The red solid line is the solid tide model calculated by *Tsoft*. There exist four prolonged power outages marked in the Figure, and the other intervals were caused by laser auto-relock.

136 bration noise is very efficient for stability and long-term measurements of our atom gravime-  
 137 ter.

138 To verify the long-term stable working ability of our AG, USTC-AG11 performs  
 139 a continuous running from Jul. 1st to Dec. 9th 2020 under an unattended mode. Fig.3  
 140 shows the continuous solid tide observation over five months. The black points are the  
 141 gravity values measured by USTC-AG11, each black point is averaged by half hour; The  
 142 red solid curve is the solid tide model. During the measurement of  $g$ , there exist four pro-  
 143 longed power outages, marked in the Fig.3. After the first power outage, we went to the  
 144 TSS to restore the measurement of  $g$ . Meanwhile, we added the vibration noise correc-  
 145 tion method mentioned above. For the remaining three power outages, the non-professional  
 146 duty officer in TSS helped us to restore the electricity, then  $g$ -measurements start after  
 147 frequency auto-relock. Fig.3 not only exhibits that a good match between the measured  
 148 data and the tide model, but also illustrates the robustness, the long-term stable and  
 149 drift-free working ability of USTC-AG11.

150 To characterize the stability of our AG, we randomly pick out two consecutive 48-  
 151 hour periods in each month during the whole measurement. As shown in Fig.4, the red  
 152 dots is the residue data obtained from the measured gravity data minus the theoretical  
 153 solid tide data, each dot is averaged by half-hour, the error bar represents the uncertainty  
 154 of the half-hour measured gravity data, about  $1\mu\text{Gal}$ . Meanwhile, we also calculate the  
 155 uncertainty between each half-hour measured gravity data, the standard deviation of each  
 156 consecutive 48-hour is marked in this figure, the long-term stability of USTC-AG11 is  
 157 only about  $1.3\mu\text{Gal}$  to  $2.2\mu\text{Gal}$ . This performance is comparable to the best commer-  
 158 cial gravimeter FG-5(X). Actually, considering the other environment variations, such  
 159 as the atmospheric pressure, polar motion and groundwater subsidence, the performance  
 160 of our AG would even be better. During this long-term measurement period, there are

**Figure 4.** Typical residue data from a consecutive 48-hour period in each month. Each red point is obtained by a half hour averaged, and error bars represent the uncertainty (about 1  $\mu\text{Gal}$ ) during the half measured gravity data. At the same time, we calculate the standard deviations of a consecutive 48-hour period picking up randomly from each month, and the uncertainty is 1.3  $\mu\text{Gal}$  to 2.2  $\mu\text{Gal}$ .

161 no professionals on site and any extra protection. Even more surprising, after several pro-  
 162 longed power outages caused by local infrastructure, we are still able to restart the mea-  
 163 surement of  $g$  via remotely accessing to the host computer when the electric supply is  
 164 restored.

## 165 4 Conclusion and Prospect

166 In this paper, we report the performance of a continuous running of a compact atom  
 167 gravimeter USTC-AG11. It is transported over 2200 kilometers from Shanghai to Yun-  
 168 nan province, and deployed in a seismic station with unattended mode. We realized the  
 169 continuous gravity measurement over five months from Jul. 1st to Dec. 9th, 2020. The  
 170 robustness and stability of our atom gravimeter is well verified. We established a com-  
 171 pact optical package and laser frequency auto-relock module, and the tight fit between  
 172 them in control timing offers the possibility of long-term gravity measurement. By us-  
 173 ing the efficient vibration correction method, we obtained a good sensitivity of  $38 \mu\text{Gal}/\sqrt{\text{Hz}}$ ,  
 174 about  $1 \mu\text{Gal}$  for 1200 seconds. We present an excellent performance of this atom gravime-  
 175 ter in a field application, the measured  $g$  values and the tide model data shows a good  
 176 match during whole measurement, with the uncertainty for only about  $2 \mu\text{Gal}$ . This per-  
 177 formance is comparable to or even better than the best commercial gravimeter FG-5(X).  
 178 Atom gravimeters are expected to become the priority for long-term precision absolute  
 179 gravity measurements, they are likely to play important roles in geophysics, geodesy, or  
 180 geological disasters observation in the near future.

## 181 Data Availability Statement

182 All of the values measured by our cold atom gravimeter are publicly accessed <https://data.mendeley.com/da>  
 183 The software for calculating the Earth solid tide model data is here: <https://seismologie.oma.be/en/downloads/ts>  
 184 The software for Allan standard deviation is here: <https://alavar.software.informer.com/5.2/>.
